EDUCATION TO INNOVATION

College of Technology

Bachelor of Technology (Computer Engineering)

Semester:	VI	**Academic Year:**	2025-26
Subject Name:	Internet of Things	**Subject Code:**	1010043320

Question Bank

UNIT-1

Sr No.	Question Text	Marks	CO Number
1	What is the Internet of Things? Briefly explain its core concept.	3	CO1
2	Explain what qualifies as a "Thing" in the context of IoT. Give two examples.	3	CO1
3	State three distinct differences between IoT and Wireless Sensor Networks (WSN).	3	CO1
4	List any three essential characteristics of an IoT system.	3	CO1
5	Briefly describe the relationship between IoT and Cyber-Physical Systems (CPS).	3	CO1
6	Name any three technologies that play a crucial role in enabling IoT.	3	CO1
7	Discuss the role of IoT in "Smart Cities" with at least two specific use cases (e.g., traffic management, waste management).	4	CO1
8	Explain the challenges of **Security** and **Scalability** in IoT implementation.	4	CO1
9	Briefly explain the function of the **Perception Layer** and the **Network Layer** in the IoT architecture.	4	CO1
10	Differentiate between **IoT Level 1** and **IoT Level 2** systems with appropriate diagrams or examples.	4	CO1

11	Draw and explain the 4-layer or 5-layer IoT Stack in detail. Describe the specific function of each layer (Perception, Transport, Processing, Application).	8	CO1
12	"IoT is not just about connecting things." Discuss this statement by detailing the Enabling Technologies, Characteristics, and one major Application area of IoT.	8	CO1

UNIT-2

Sr No.	Question Text	Marks	CO Number
1	Define a sensor. Explain with examples.	3	CO2
2	List three key features of ARM processors that make them suitable for IoT devices.	3	CO2
3	Differentiate between Analog and Digital sensors. Give one example of each.	3	CO2
4	Explain the concept of **GPIO** (General Purpose Input/Output) pins. How are they used to control a simple LED?	4	CO2
5	What is a Microcontroller (MCU)? How is it different from a Microprocessor?	4	CO2
6	Explain the necessity of an **Analog-to-Digital Converter (ADC)** when interfacing analog sensors with a digital microcontroller.	4	CO2
7	Briefly explain the advantages of **RISC** architecture used in ARM processors over CISC architecture.	4	CO2
8	Design a simple IoT system for "Temperature Monitoring." A. List the required hardware (Sensors, MCU). B. Explain the interfacing diagram (block diagram). C. Describe the flow of data from the sensor to the user.	8	CO2
9	Compare **Arduino** (AVR) and **Raspberry Pi** (ARM) regarding their architecture, power consumption, and suitable use cases.	8	CO2

SILVER OAK UNIVERSITY

EDUCATION TO INNOVATION

UNIT-3

SR NO.	Question Text	Marks	CO Number
1	Explain Protocols for IoT	8	CO3
2	What is Protocol? Explain Messaging protocols.	8	CO3
3	Explain Transport protocols.	8	CO3
4	Write a short not: IPv4	8	CO3
5	Write a short not: IPv6	8	CO3
6	Difference between Ipv4 and IPv6	4	CO3
7	Explain IEEE802.15.4	4	CO3

UNIT- 4

SR NO.	Question Text	Marks	CO Number
1	Write a short not: Cloud for IoT	8	CO3
2	Explain IoT and cloud.	8	CO3
3	Explain Fog computing.	8	CO3
4	Different between IoT and cloud	4	CO3
5	Write a short not: Security in cloud	4	CO3

UNIT- 5

SR NO.	Question Text	Marks	CO Number
1	Write a Various application of IoT.	4	CO4
2	Explain following application of IoT: Food and Healthcare.	8	CO4
3	Explain following application of IoT: Water quality, Retail	8	CO4
4	Explain Driver Assistance application of IoT.	4	CO4

5	Explain following application of IoT: Warehouse and Collision impact	8	CO4
6	Explain following application of IoT: Smart Cities and Smart Grid	8	CO4

UNIT- 6

SR NO.	Question Text	Marks	CO Number
1	Explain Arduino.	4	CO4
2	Explain Raspberry Pi.	4	CO4
3	Draw and Explain Architecture of Arduino.	8	CO4
4	Draw and Explain Architecture of Raspberry Pi.	4	CO4
5	What is Arduino. Explain Programming and Application Raspberry in Arduino.	8	CO4
6	What is Raspberry Pi. Explain Programming and Application in Raspberry Pi	8	CO4

UNIT- 7

SR NO.	Question Text	Marks	CO Number
1	Explain IoT Security.	4	CO5
2	Explain Various security issues and need.	4	CO5
3	Draw and Explain Architecture of IoT Security.	8	CO5
4	Explain requirement of IoT Security.	4	CO5
5	Explain challenges and algorithms IoT Security.	8	CO5

UNIT 1 — Introduction to Internet of Things

Q1. [3 Marks] What is the Internet of Things? Briefly explain its core concept.

Definition:

The Internet of Things (IoT) refers to the network of physical objects or things that are embedded with sensors, software, and other technologies for the purpose of connecting and exchanging data with other devices and systems over the internet. These objects can range from ordinary household items to sophisticated industrial tools.

Core Concept:

The core concept of IoT is simple — connect physical devices to the internet so they can collect data, communicate with each other, and take actions automatically without human involvement. The main idea is that every physical object around us can be given a digital identity and the ability to sense, communicate, and respond.

IoT is not just limited to connected or networked devices. In a broad way, IoT devices are interconnected computing devices embedded in everyday objects, enabling them to send and receive data. This makes everyday objects smarter and more useful. For example, a simple thermostat connected to the internet can learn your schedule and automatically adjust temperature to save energy. A street light with sensors can turn on and off based on actual ambient light conditions.

The basic components needed for any IoT system are: a Sensor/Actuator to interact with the environment, a Communication Module to connect to the internet, a Processing Unit (microcontroller or microcomputer) to process data, and a Cloud or Local Server to store and analyze data.

Q2. [3 Marks] Explain what qualifies as a 'Thing' in the context of IoT. Give two examples.

What is a 'Thing' in IoT?

In the context of IoT, a 'Thing' refers to any physical object or device that has a unique identity, the ability to sense or collect data from its environment, and the capability to communicate that data over a network — usually the internet. A 'Thing' does not have to be an electronic gadget by default. It can be any physical object that is embedded with sensors, software, and communication technology.

A 'Thing' in IoT must have: (1) an identity — usually a unique IP address so it can be identified on the network, (2) sensing capability — to detect or measure something from its environment, and (3) communication capability — to send that data to another device or system.

Categories of Things in IoT:

- Sensors — devices that detect changes in the environment and send the data to other devices. Example: a temperature sensor in a room.
- Actuators — components that perform physical actions based on received data. Example: a motor that opens a valve.
- Smart Devices — gadgets like smartwatches, smart TVs, and home assistants that interact with the IoT network.
- Embedded Systems — microcontrollers and embedded systems that control IoT devices.

Two Examples:

Example 1 — Smart Thermostat: A thermostat connected to the internet qualifies as a 'Thing.' It has a temperature sensor to measure room temperature, a processor to compare with the set point, and

a Wi-Fi module to communicate with a smartphone app. The user can remotely control heating or cooling from anywhere.

Example 2 — Smartwatch: A smartwatch is a 'Thing' in IoT. It has sensors to measure heart rate, steps, sleep patterns, and GPS location. It connects to a smartphone via Bluetooth and uploads health data to the cloud for analysis and monitoring.

Q3. [3 Marks] State three distinct differences between IoT and Wireless Sensor Networks (WSN).

Introduction:

WSN (Wireless Sensor Network) is often confused with IoT because both involve sensors and wireless communication. However, they are different in terms of scope, capabilities, and objectives. WSN is actually a subset of IoT — it focuses only on sensor data collection, while IoT is much broader.

Feature	IoT (Internet of Things)	WSN (Wireless Sensor Network)
Scope	Very broad — covers sensing, actuation, analytics, cloud, user apps	Narrow — mainly focused on data collection from sensor nodes
Components	Sensors, Actuators, Controllers, Cloud, User Interface, Smart Devices	Only sensor nodes and a base station/gateway
Actuation	IoT supports actuators — devices can take physical actions based on data	WSN generally does not support actuation — it only collects data
Internet Connectivity	IoT devices are always connected to the internet and communicate globally	WSN nodes may or may not be connected to the internet
Intelligence	IoT includes AI, machine learning, and advanced data analytics	WSN has limited processing — mostly raw data collection
Applications	Smart cities, healthcare, agriculture, industrial automation, retail, etc.	Environmental monitoring, military surveillance, precision agriculture

In short, WSN is only about coordinated data collection from sensor nodes. IoT is broader — it adds actuators, intelligence, advanced analytics, cloud connectivity, and user interfaces on top of what WSN offers.

Q4. [3 Marks] List any three essential characteristics of an IoT system.

Introduction:

An IoT system is not just about connecting devices. It must have certain characteristics that define its behavior and capability. These characteristics make IoT systems different from ordinary networked systems. There are 7 key characteristics of IoT, out of which three essential ones are explained below.

1. Connectivity

Connectivity is the most fundamental characteristic of IoT. Every device in an IoT system must be able to communicate and exchange data with other devices and systems. This includes device-to-device (D2D), device-to-server, and device-to-gateway communication. Connectivity can be achieved through various technologies like Wi-Fi, Bluetooth, Zigbee, NFC, and cellular networks. Without connectivity, an IoT device is just a standalone sensor with no ability to contribute to the larger system.

2. Intelligence (Smart Processing)

IoT systems are not just about collecting data — they must be able to process that data and make intelligent decisions. Intelligence in IoT refers to the ability of the system to analyze data, recognize patterns, and take automated actions without human intervention. For example, a smart irrigation system that analyses soil moisture data and automatically turns on the water pump — without a human pressing any button — demonstrates intelligence. This is often powered by machine learning algorithms at the cloud or edge layer.

3. Sensing

Sensing is the capability of IoT devices to detect changes in the physical environment. Sensors are the eyes and ears of an IoT system. They convert physical parameters like temperature, humidity, pressure, light, and motion into electrical signals that can be processed. Without sensing, no data can be collected, making it the starting point of the entire IoT data pipeline.

Q5. [3 Marks] Briefly describe the relationship between IoT and Cyber-Physical Systems (CPS).

Introduction:

Both IoT and CPS (Cyber-Physical Systems) involve the integration of physical and digital systems. They are closely related but they are NOT the same thing. Understanding their relationship helps in designing better interconnected systems.

What is CPS?

A Cyber-Physical System (CPS) is a complex system that tightly integrates computation, networking, and physical processes. In CPS, physical processes are monitored and controlled by computer-based algorithms, and the feedback from the physical world directly affects computation and vice versa. CPS is used in applications like aircraft control systems, smart power grids, autonomous vehicles, and industrial automation.

Relationship between IoT and CPS:

- IoT can be considered a key component or enabler of CPS. IoT provides the sensing and connectivity infrastructure that CPS relies on.
- CPS is more complex and autonomous than IoT. For example, an aircraft control system involves mechanical engineering, electrical engineering, control systems, and computing — all working together. IoT alone is just one part of this.
- IoT focuses on connecting 'things' and collecting data. CPS focuses on using that data to control and coordinate physical processes in real-time.
- CPS emphasizes the feedback loop between computation and physical processes, while IoT emphasizes data collection, communication, and cloud analytics.

In summary, IoT is a component inside CPS. CPS is more complex and autonomous, involving multiple engineering fields working together. IoT provides the device-level sensing and connectivity, while CPS uses that information to actively control and manage physical systems.

Q6. [3 Marks] Name any three technologies that play a crucial role in enabling IoT.

Introduction:

IoT does not work in isolation. It depends on a set of enabling technologies that provide the infrastructure, tools, and capabilities needed to connect devices, process data, and take intelligent actions. Without these enabling technologies, IoT systems would not be able to function at the scale and complexity required today.

1. Wireless Communication Technologies

Wireless communication is the backbone of IoT connectivity. Technologies like Wi-Fi, Bluetooth, Zigbee, NFC, and cellular networks (4G/5G) allow IoT devices to communicate with each other and with the internet without physical cables. Zigbee and Bluetooth Low Energy (BLE) are particularly

popular for IoT because they consume very little power — which is critical for battery-operated IoT devices. Without wireless communication, deploying IoT devices in large-scale environments like smart cities or agricultural fields would be practically impossible.

2. Cloud Computing

Cloud computing provides the scalable storage and processing power that IoT systems need to handle the massive amounts of data generated by millions of connected devices. Cloud platforms like AWS IoT, Microsoft Azure IoT Hub, and Google Cloud IoT allow IoT devices to upload their data to central servers where it can be stored, processed, and analyzed. Cloud also enables remote access — a user can monitor and control their IoT devices from anywhere in the world through a smartphone app. Service models like IaaS, PaaS, and SaaS make it easier to build and deploy IoT solutions.

3. Artificial Intelligence and Machine Learning

AI and ML play a critical role in turning raw sensor data into meaningful insights and automated actions. Machine learning algorithms can analyze patterns in IoT data, detect anomalies, make predictions, and enable autonomous decision-making. For example, in a predictive maintenance system, ML models analyze vibration and temperature data from industrial machines to predict failures before they happen. AI also powers natural language processing in voice-controlled IoT devices like Amazon Alexa and Google Home.

Q7. [4 Marks] Discuss the role of IoT in 'Smart Cities' with at least two specific use cases.

Introduction:

A Smart City is a city that uses digital technology and IoT-based systems to enhance the quality of life for its citizens, improve the efficiency of urban services, and reduce resource consumption. IoT is the core technology that powers smart cities by connecting infrastructure, services, and citizens through a network of sensors and communication devices. Smart city applications cover almost every aspect of urban life — from traffic management to public safety.

Role of IoT in Smart Cities:

IoT enables city authorities to collect real-time data from various parts of the city through sensors deployed in infrastructure, public spaces, and transportation systems. This data is sent to a central cloud platform where it is analyzed to make data-driven decisions. The goal is to automate and optimize city services so they work more efficiently and respond to real-time conditions rather than following fixed schedules.

Use Case 1 — Smart Traffic Management:

Traditional traffic signals operate on fixed timers regardless of actual traffic volume. In a smart city, IoT sensors and cameras are installed at intersections to monitor the number of vehicles in real-time. This data is sent to a central traffic management system that dynamically adjusts signal timings to reduce congestion. For example, if one lane is heavily congested, the system increases green signal time for that lane automatically. Additionally, if an emergency vehicle is approaching, traffic signals along its route can be pre-cleared. This reduces travel time, lowers fuel consumption, and decreases air pollution in the city.

Use Case 2 — Smart Waste Management:

In traditional cities, garbage trucks follow fixed routes regardless of whether dustbins are full or not. In a smart city, IoT sensors are installed inside dustbins to monitor their fill levels. When a dustbin is nearly full, it sends an alert to the waste management center. The system then dynamically plans collection routes so that trucks only visit bins that need emptying. This reduces the number of collection trips, saves fuel, lowers carbon emissions, and prevents overflow of garbage bins in public areas — improving overall cleanliness and hygiene of the city.

Q8. [4 Marks] Explain the challenges of Security and Scalability in IoT implementation.

Introduction:

IoT implementation comes with several challenges. Among them, Security and Scalability are the two most critical and complex challenges that developers and organizations face. These challenges affect both the design and the long-term operation of IoT systems.

Challenge 1 — Security:

Security in IoT means protecting devices, networks, data, and users from unauthorized access, cyberattacks, and misuse. IoT devices are particularly vulnerable to security threats because many of them have limited computing resources, which means they cannot run heavy security software. Common security threats in IoT include:

- Device Security: IoT devices often run outdated firmware and lack regular security updates. Attackers can exploit these vulnerabilities to gain control of the device.
- Network Security: If communication between IoT devices and the cloud is not encrypted, attackers can intercept and read sensitive data — this is called a man-in-the-middle attack.
- Data Security: Large volumes of personal and sensitive data are collected by IoT devices. A data breach can expose private information of millions of users.
- Weak Authentication: Many IoT devices use simple or default passwords, making it easy for attackers to gain unauthorized access.

To address security, solutions include using strong encryption protocols (like TLS/DTLS), implementing multi-factor authentication, regular firmware updates, and secure boot mechanisms.

Challenge 2 — Scalability:

Scalability in IoT refers to the ability of the system to handle a growing number of connected devices without losing performance. Currently, there are billions of IoT devices connected globally, and this number is expected to grow exponentially. Managing this scale creates several problems:

- Network Congestion: As millions of devices try to communicate simultaneously, the network can become congested and slow.
- Data Volume: Billions of devices generate enormous amounts of data every second. Storing, processing, and analyzing this data requires massive and scalable infrastructure.
- IP Address Exhaustion: IPv4 addresses are limited. With billions of IoT devices, IPv6 adoption is essential for scalability.
- Management Complexity: Managing firmware updates, configurations, and security patches for millions of devices is a huge operational challenge.

Solutions for scalability include using IPv6 for device addressing, adopting fog and edge computing to distribute processing load, and using cloud platforms that offer elastic scaling.

Q9. [4 Marks] Briefly explain the function of the Perception Layer and the Network Layer in the IoT architecture.

Introduction:

IoT architecture is organized into multiple layers, each responsible for a specific function in the data journey from the physical world to the user. The two foundational layers of IoT architecture are the Perception Layer (also called Device Layer) and the Network Layer (also called Communication Layer). Understanding these layers is key to understanding how IoT systems work.

1. Perception Layer (Physical/Sensor Layer):

The Perception Layer is the first and lowest layer of the IoT architecture. It is the physical layer that directly interacts with the environment. This layer consists of all the sensing and actuating devices — the 'things' in IoT.

Functions of the Perception Layer:

- It collects data from the physical environment using sensors. For example, a temperature sensor measures ambient temperature, a motion sensor detects movement, and a pressure sensor measures air pressure.
- It performs initial data conversion — sensors convert physical quantities (like heat, light, pressure) into electrical signals that can be processed.
- Actuators in this layer can also perform physical actions based on commands received from higher layers. For example, a motor starting, a valve opening, or an LED turning on.

This layer is the starting point of all IoT data. Without accurate sensing at this layer, the entire IoT system loses reliability.

2. Network Layer (Communication Layer):

The Network Layer is responsible for transmitting the data collected by the Perception Layer to other parts of the system — such as fog nodes, servers, or the cloud. This layer acts as the communication highway of the IoT system.

Functions of the Network Layer:

- It uses various wireless and wired technologies like Wi-Fi, Bluetooth, Zigbee, NFC, Ethernet, and cellular networks (4G/5G) to transmit data.
- It handles data routing, addressing (using IP addresses), and protocol selection based on the type of device and network available.
- It ensures reliable and secure data transmission between devices and the cloud.

This layer determines the speed, range, and reliability of communication in an IoT system. The choice of network technology depends on factors like power consumption, data rate, and range.

Q10. [4 Marks] Differentiate between IoT Level 1 and IoT Level 2 systems with appropriate examples.

Introduction:

IoT systems are classified into levels based on the number of sensors used, where data analysis takes place, and where data is stored. These levels help in understanding the complexity and capability of different IoT deployments. Level 1 and Level 2 represent the two simplest forms of IoT architecture.

Feature	IoT Level 1	IoT Level 2
Number of Sensors	Single sensor/actuator node	Single sensor/actuator node (but faster data rate)
Data Analysis	Done locally on the device itself	Done locally on the device itself
Data Storage	Data stored locally (on the device)	Data stored in the cloud
Internet Usage	Not connected to cloud; only local	Connected to cloud for storage only
Cost	Very low cost	Slightly higher due to cloud storage
Example	Simple standalone temperature alarm	Home temperature logger that uploads readings to cloud

IoT Level 1 — Detailed Explanation:

In IoT Level 1, there is a single sensing node and all data analysis is done locally on the device itself. The device does not connect to the internet or cloud. Data is stored locally on the device's memory. This is the simplest form of IoT. Example: A standalone smoke alarm that detects smoke and triggers a local buzzer. No internet, no cloud — everything happens on the device itself.

IoT Level 2 — Detailed Explanation:

In IoT Level 2, there is still a single sensing node and analysis is done locally, but now the device is connected to the cloud for data storage. The device uploads its data to the cloud after local

processing. This allows historical data to be stored and accessed remotely. Example: A temperature monitoring device that measures temperature every minute, does basic analysis locally (like triggering an alarm if temperature exceeds a threshold), but also uploads all readings to a cloud platform so the user can view historical temperature trends from their smartphone.

Q11. [8 Marks] Draw and explain the 4-layer or 5-layer IoT Stack in detail.

Introduction:

The IoT Stack refers to the layered architecture that defines how data flows from physical devices all the way to end-user applications. Just like the OSI model in networking, the IoT Stack organizes IoT functionality into layers where each layer has a specific role. The 5-layer IoT Stack (also sometimes presented as a 6-layer or 7-layer model) is the most comprehensive and widely taught model.

The 7-Layer IoT Stack:

Layer 1 — Physical/Sensor Layer (Device Layer):

This is the lowest layer. It consists of all the physical sensors and actuators that interact directly with the environment. Sensors collect data like temperature, humidity, pressure, light, and motion. Actuators perform physical actions like opening a valve or switching on a motor. This is where all IoT data originates. Examples: LM35 temperature sensor, PIR motion sensor, relay module.

Layer 2 — Processing and Control Layer:

This layer contains the microcontrollers and microcomputers that process the raw data received from sensors. The controller reads sensor values, applies logic (like checking if temperature has exceeded a threshold), and either acts locally or prepares the data for transmission. Examples: Arduino Uno, ESP8266, Raspberry Pi.

Layer 3 — Hardware Interface Layer:

This layer handles the communication protocols between sensors and the controller. Protocols like SPI, I2C, UART, RS232, and CAN bus are used here to define how data is transferred between components at the hardware level.

Layer 4 — RF Communication Layer (Network Layer):

This layer is responsible for wireless communication — transmitting processed data from the device to a gateway or directly to the cloud. Technologies used here include Wi-Fi, Bluetooth, Zigbee, NFC, RFID, and cellular networks (4G/5G). The choice of technology depends on range, power, and data rate requirements.

Layer 5 — Session/Messaging Layer:

This layer handles the application-level messaging protocols that govern how data is sent and received over the network. Key protocols here include MQTT (lightweight publish-subscribe), CoAP (for constrained devices), SSH, and FTP. MQTT is the most popular IoT messaging protocol because of its low bandwidth usage.

Layer 6 — User Experience Layer:

This layer deals with how the end-user or application developer interacts with the IoT system. It includes mobile apps, web dashboards, APIs, and scripting interfaces. This layer converts raw IoT data into meaningful visualizations and controls that users can understand and interact with.

Layer 7 — Application Layer:

This is the topmost layer where actual IoT applications run. Smart city dashboards, healthcare monitoring apps, industrial SCADA systems, and home automation apps all exist at this layer. This is the layer that end-users directly experience. It takes processed and analyzed data from lower layers and presents it in a meaningful and actionable form.

Data Flow Summary:

Physical Environment → Sensor (Layer 1) → Microcontroller (Layer 2) → Communication Protocol (Layer 3) → Wireless Transmission (Layer 4) → Messaging Protocol (Layer 5) → User Interface (Layer 6) → Application (Layer 7)

Q12. [8 Marks] **"IoT is not just about connecting things." Discuss by detailing Enabling Technologies, Characteristics, and one major Application area.**

Introduction:

The statement 'IoT is not just about connecting things' is absolutely correct. Many people think IoT is simply about putting devices on the internet, but in reality, IoT is a complete ecosystem that involves sensing, communication, intelligence, analytics, cloud services, and real-world action. To understand the full scope of IoT, we need to look at its Enabling Technologies, core Characteristics, and real Application areas.

Part 1 — Enabling Technologies:

IoT depends on multiple enabling technologies that work together:

- Wireless Communication (Wi-Fi, Bluetooth, Zigbee, NFC, Cellular) — provides connectivity between devices.
- Cloud Computing (IaaS, PaaS, SaaS) — provides scalable storage and processing for IoT data.
- Big Data Analytics (4Vs: Volume, Variety, Velocity, Veracity) — enables analysis of massive IoT data streams.
- Artificial Intelligence and Machine Learning — enables intelligent and automated decision-making based on data.
- Embedded Systems (Arduino, Raspberry Pi, NodeMCU) — provides the hardware platform for IoT devices.
- Blockchain — provides secure and tamper-proof data transactions in IoT networks.
- Cybersecurity tools — protect IoT devices and networks from threats.

Part 2 — Core Characteristics:

IoT systems must exhibit specific characteristics to function properly: Connectivity (devices must communicate), Intelligence (devices must make smart decisions), Sensing (devices must collect real-world data), Expressing (actuators must respond to data), Energy Efficiency (devices must conserve power), Scalability (system must handle millions of devices), and Interoperability (devices from different manufacturers must work together using standard protocols).

Part 3 — Application Area: Healthcare IoT

Healthcare is one of the most impactful application areas of IoT. IoT in healthcare goes far beyond just connecting a device to the internet:

- Remote Patient Monitoring — Wearable IoT devices continuously monitor vital signs like heart rate, blood pressure, oxygen levels, and glucose levels. This data is sent to a cloud platform where doctors can monitor it in real-time, eliminating the need for the patient to physically visit a hospital for every checkup.
- Smart Hospitals — IoT devices track the location of medical equipment, monitor patient conditions in real-time, and manage hospital resources efficiently. This reduces delays and improves patient care quality.
- Medication Management — Smart pill dispensers remind patients when to take their medicine and alert caregivers if doses are missed, improving treatment adherence especially for elderly patients.

This example clearly shows that IoT in healthcare is not just about connecting devices — it involves sensors, AI analytics, cloud storage, secure communication, and intelligent decision-making working together to save lives.

UNIT 2 — Sensors, Microcontrollers & Interfacing

Q1. [3 Marks] **Define a sensor. Explain with examples.**

Definition:

A sensor is a device that detects and responds to changes in the physical environment by converting physical parameters — like temperature, humidity, pressure, light, sound, or motion — into electrical signals that can be measured, interpreted, or processed by a microcontroller or computer. Sensors are the fundamental input components of any IoT system. They act as the 'eyes and ears' of IoT — without sensors, no data can be collected from the real world.

How a Sensor Works:

A sensor monitors a physical quantity in its environment. When the physical quantity changes, the sensor produces a corresponding change in an electrical signal (voltage, current, or resistance). This electrical signal is then read by a microcontroller through an analog or digital input pin. The microcontroller processes this data and takes appropriate action.

Types of Sensors with Examples:

- Temperature Sensors — Measure heat changes in the environment. Examples: LM35 (produces an analog voltage proportional to temperature), RTD (Resistance Temperature Detector), Thermocouple, Thermistor.
- Proximity/Obstacle Sensors — Detect the presence or absence of an object. Examples: IR sensor (uses infrared light to detect objects), HC-SR04 Ultrasonic sensor (uses sound waves to measure distance).
- Pressure Sensors — Measure pressure of gases or liquids. Examples: Barometer, Manometer.
- Light Sensors — Detect the intensity of light. Examples: LDR (Light Dependent Resistor — resistance decreases as light increases), Photodiode, Phototransistor.
- Motion Sensors — Detect movement or orientation. Examples: MPU-6050 (accelerometer + gyroscope), PIR sensor.
- Chemical/Gas Sensors — Detect chemical properties or gas presence. Examples: pH sensor, MQ-02 Gas sensor, MQ-05 smoke sensor.
- Humidity Sensors — Measure moisture level in the environment. Examples: DHT11, DHT22, Hygrometer.

Q2. [3 Marks] **List three key features of ARM processors that make them suitable for IoT devices.**

Introduction:

ARM (Advanced RISC Machine) processors are the most widely used processor architecture in embedded systems and IoT devices today. They power everything from smartphones to industrial sensors. Their suitability for IoT comes from several key features that align perfectly with the requirements of IoT devices — which need to be small, low-power, and efficient.

Feature 1 — Low Power Consumption:

IoT devices are often battery-operated and deployed in remote locations where recharging is not possible. ARM processors are designed with a RISC (Reduced Instruction Set Computing) architecture that executes simple instructions in fewer clock cycles, which directly reduces power consumption. The ARM Cortex-M0 variant, for example, is designed for ultra-low power operation — it can run on a coin cell battery for months or even years. This is critical for IoT sensors deployed in agriculture fields, smart meters, and wearables.

Feature 2 — High Performance with Small Size:

ARM processors deliver excellent computational performance despite being physically very small. IoT devices need to be compact, and ARM's chip design allows high processing capability in a small form factor. The ARM Cortex-M4 variant includes DSP (Digital Signal Processing) extensions, allowing it to process complex sensor data — like audio signals or accelerometer data — efficiently. This balance of size and performance makes ARM ideal for IoT applications ranging from simple sensor nodes to complex edge computing devices.

Feature 3 — Scalable Architecture (Cortex-M Series):

ARM offers a range of Cortex-M variants that scale from basic to advanced, allowing designers to choose the right level of capability for their specific IoT application: Cortex-M0 (ultra-low power, basic tasks), Cortex-M3 (higher performance for complex applications), and Cortex-M4 (DSP extensions for signal processing). This scalability means the same ecosystem of tools and knowledge applies across simple IoT sensors and complex IoT gateways.

Q3. [3 Marks] **Differentiate between Analog and Digital sensors. Give one example of each.**

Introduction:

Sensors can be broadly classified into two types based on the nature of the output signal they produce: Analog sensors and Digital sensors. Understanding this difference is important because it determines how a sensor is interfaced with a microcontroller.

Feature	Analog Sensor	Digital Sensor
Output Type	Continuous signal — varies smoothly with the measured quantity	Discrete signal — either HIGH (1) or LOW (0)
Signal Nature	Produces a voltage or current that changes proportionally	Produces binary data (HIGH/LOW or serial data like I2C/SPI)
Interfacing	Requires an ADC (Analog-to-Digital Converter) to connect to MCU	Can be connected directly to GPIO pins or via I2C/SPI/UART
Resolution	Higher resolution — captures fine gradations of data	Limited by the number of digital output states
Complexity	Simpler hardware, but needs ADC for digital processing	Slightly more complex, but easier to interface digitally
Noise Sensitivity	More sensitive to electrical noise	Less sensitive — noise only matters near the threshold
Example	LM35 Temperature Sensor	PIR Motion Sensor (HC-SR501)

Example of Analog Sensor — LM35:

The LM35 is a temperature sensor that produces an analog voltage output directly proportional to temperature in Celsius. For every 1°C increase in temperature, the output voltage increases by 10mV. So at 25°C, the output is 250mV. This analog voltage is connected to the ADC pin of a microcontroller like Arduino, which converts it to a digital value (0–1023 for Arduino's 10-bit ADC) that can then be used to calculate the actual temperature.

Example of Digital Sensor — PIR Motion Sensor (HC-SR501):

The PIR (Passive Infrared) motion sensor detects human or animal movement by measuring infrared radiation. Its output is digital — when motion is detected, the output pin goes HIGH (3.3V or 5V). When no motion is detected, it goes LOW (0V). This output is directly connected to a digital GPIO pin of the microcontroller — no ADC needed.

Q4. [4 Marks] **Explain the concept of GPIO (General Purpose Input/Output) pins. How are they used to control a simple LED?**

What is GPIO?

GPIO stands for General Purpose Input/Output. GPIO pins are the programmable digital pins available on microcontrollers and microcomputers like Arduino, Raspberry Pi, and ESP8266. These pins can be configured by the programmer to act either as an INPUT (to read data from sensors) or as an OUTPUT (to send signals to actuators or devices). The 'General Purpose' part means these pins are not dedicated to any fixed function — the programmer decides what they do.

Key Properties of GPIO:

- Each GPIO pin can be set to either INPUT mode (to read voltage levels from external devices) or OUTPUT mode (to write voltage levels to external devices).
- In digital mode, a GPIO pin reads or writes either HIGH (typically 3.3V or 5V) or LOW (0V).
- On Arduino Uno, there are 14 digital GPIO pins. On Raspberry Pi 4, there are 40 GPIO pins.
- GPIO pins can also be configured for special functions like PWM (Pulse Width Modulation), I2C, SPI, and UART in some microcontrollers.
- Each GPIO pin has a maximum current rating — on Arduino, this is 40mA per pin. Exceeding this can damage the microcontroller.

Using GPIO to Control a Simple LED:

To control an LED using GPIO on an Arduino:

1. Hardware Setup: Connect the positive leg (anode) of the LED to digital pin 13 of Arduino through a 220-ohm resistor (to limit current). Connect the negative leg (cathode) to the GND pin.
2. Configure the pin: In the Arduino program, use pinMode(13, OUTPUT) to set pin 13 as an output pin. This tells the microcontroller that pin 13 will be sending signals, not reading them.
3. Turn LED ON: Use digitalWrite(13, HIGH) to send 5V to pin 13. This provides current through the LED, making it glow.
4. Turn LED OFF: Use digitalWrite(13, LOW) to set pin 13 to 0V, cutting off current and turning the LED off.
5. Blink: By repeatedly calling digitalWrite(13, HIGH), delay(1000), digitalWrite(13, LOW), delay(1000) inside the loop() function, the LED will blink on and off every second.

This simple LED blinking example demonstrates the fundamental concept of GPIO — the microcontroller controls physical hardware by switching its digital output pins HIGH or LOW.

Q5. [4 Marks] **What is a Microcontroller (MCU)? How is it different from a Microprocessor?**

What is a Microcontroller (MCU)?

A Microcontroller (MCU) is a compact integrated circuit (IC) that is designed to govern a specific operation in an embedded system. It is often called a 'computer on a chip' because it integrates all the components of a computer — processor, memory, and input/output peripherals — on a single chip. This self-contained nature makes it ideal for IoT devices, embedded systems, and control applications where size, power, and cost are critical factors.

A microcontroller typically contains: a CPU (Central Processing Unit) for processing instructions, ROM/Flash memory to store the program code, RAM for temporary data storage, EEPROM for non-volatile data storage, GPIO pins for interfacing with sensors and actuators, and communication interfaces like UART, SPI, and I2C built directly on the chip.

Example: Arduino Uno uses the ATmega328P microcontroller — 32KB Flash, 2KB SRAM, 14 digital I/O pins, 6 analog pins, all on a single chip.

Feature	Microcontroller (MCU)	Microprocessor (MPU)
Definition	Complete computer on a chip — CPU + memory + I/O all integrated	Only the CPU — requires external memory and peripherals
Memory	Built-in RAM, ROM/Flash, EEPROM on the chip	External RAM and ROM chips needed
I/O Peripherals	Built-in GPIO, UART, SPI, I2C, ADC on chip	External interface chips required
Cost	Low cost — single chip solution	Higher cost — needs many external components
Power Consumption	Very low power — ideal for battery IoT devices	Higher power consumption
Speed	Lower clock speed (8 MHz – 240 MHz typically)	Very high clock speed (1 GHz – 4 GHz)
OS Support	Generally no OS required (bare metal programming)	Requires an OS like Linux or Windows
Use Case	Embedded systems, IoT sensors, control applications	Laptops, desktops, smartphones, complex computing
Examples	ATmega328P (Arduino), ESP8266, STM32	Intel Core i5, AMD Ryzen, Apple M1

Q6. [4 Marks] Explain the necessity of an ADC when interfacing analog sensors with a digital microcontroller.

Introduction:

In IoT systems, many important sensors produce analog output signals — continuous electrical signals whose voltage varies proportionally with the physical quantity being measured. However, microcontrollers are fundamentally digital devices — they can only understand discrete binary values (0s and 1s). This creates a fundamental incompatibility between the analog world of sensors and the digital world of microcontrollers. The ADC (Analog-to-Digital Converter) is the bridge that resolves this incompatibility.

Why Analog Sensors Cannot Connect Directly to Digital Pins:

A digital GPIO pin of a microcontroller can only read two states: HIGH (5V or 3.3V) or LOW (0V). But an analog sensor like LM35 produces a continuously varying voltage — for example, 250mV at 25°C, 300mV at 30°C, etc. If you connected this directly to a digital pin, the microcontroller would only see HIGH or LOW and lose all the precise measurement information. It would not know if the temperature was 25°C or 30°C — just that it's either above or below the threshold voltage.

What ADC Does:

The ADC converts the continuous analog voltage from the sensor into a digital number that the microcontroller can process. The conversion is done by sampling the analog voltage at regular intervals and expressing it as a binary number. The resolution of the ADC determines how precisely it can represent the analog value.

Arduino has a 10-bit built-in ADC. This means it divides the input voltage range (0V to 5V) into 2^10 = 1024 levels (0 to 1023). So if LM35 outputs 250mV (for 25°C), the ADC converts this as: ADC value = (250mV / 5000mV) × 1024 = approximately 51. The Arduino program then converts 51 back to temperature: Temperature = (ADC_value × 5000mV / 1024) / 10 = 25°C.

Summary of ADC Necessity:

- Without ADC: Microcontroller can only detect HIGH or LOW — cannot measure precise values.
- With ADC: Microcontroller receives a digital number (0–1023 for 10-bit ADC) that accurately represents the measured physical quantity.
- ADC enables precise, quantitative measurements from the analog world.
- All analog sensors (LM35, LDR, potentiometer, pH sensor, gas sensor) require ADC for meaningful interfacing.

Q7. [4 Marks] Briefly explain the advantages of RISC architecture used in ARM processors over CISC architecture.

Introduction:

Processor architectures are classified into two main types based on the design philosophy of their instruction sets: RISC (Reduced Instruction Set Computing) and CISC (Complex Instruction Set Computing). ARM processors use RISC architecture, which is one of the main reasons they are so popular in IoT, mobile, and embedded applications. Understanding the advantages of RISC over CISC explains why ARM is the preferred choice for IoT devices.

Feature	RISC (ARM)	CISC (Intel x86)
Instruction Set	Small, simple instructions — each does one basic operation	Large, complex instructions — one instruction can do multiple operations
Execution Speed	Each instruction executes in 1 clock cycle (mostly)	Instructions may take multiple clock cycles
Hardware Complexity	Simpler hardware — fewer transistors needed	Complex hardware — more transistors for complex instruction decoding
Power Consumption	Lower power — simpler instructions need less energy	Higher power consumption
Pipelining	Easy to pipeline — improves throughput	More difficult to pipeline due to variable instruction sizes
Compiler Dependency	Relies more on compiler for optimization	Hardware itself handles complex operations
Register Usage	Uses more registers to minimize memory accesses	Uses fewer registers — relies more on memory
Examples	ARM Cortex-M, MIPS, RISC-V	Intel Core, AMD Ryzen

Key Advantages of RISC for IoT:

- Lower Power — IoT devices are often battery-operated. RISC's simpler execution uses less power per operation, extending battery life significantly.
- Faster Execution — Simple instructions execute in one clock cycle, making RISC processors faster for the same clock speed when running typical IoT tasks.
- Smaller Chip Size — Simpler hardware means fewer transistors, resulting in smaller and cheaper chips — critical for compact IoT hardware.
- Better Pipelining — RISC instructions are uniform in size and complexity, making it easier to implement efficient instruction pipelines that improve throughput.

Q8. [8 Marks] **Design a simple IoT system for 'Temperature Monitoring.'**

Introduction:

A Temperature Monitoring IoT system is one of the most common and practical IoT applications. It uses a temperature sensor to continuously measure temperature, a microcontroller to process the data, a communication module to send the data to the cloud, and a user interface to display and monitor temperature remotely. This system is used in server rooms, cold storage, greenhouses, hospitals, and industrial facilities.

A. Required Hardware:

- Sensor: LM35 Temperature Sensor — analog output, 10mV/°C, easy to interface with Arduino's ADC.
- Microcontroller/MCU: Arduino Uno (ATmega328P) — reads analog data from LM35, processes it, and sends to cloud.
- Communication Module: ESP8266 Wi-Fi Module — connects Arduino to the internet and uploads data to the cloud platform.
- Power Supply: 5V USB power bank or DC adapter.
- Alert Component: Buzzer or LED for local alerts when temperature exceeds a threshold.
- Cloud Platform: ThingSpeak, Firebase, or AWS IoT Core — for data storage, visualization, and remote access.

B. Interfacing Diagram (Block Diagram Description):

LM35 (Sensor) → Analog Pin A0 of Arduino → Arduino processes and converts to °C → ESP8266 (via UART) → Wi-Fi Network → Cloud Platform → Smartphone/Web Dashboard

Additionally: Arduino → Buzzer/LED (for local alarm when temperature > threshold)

C. Flow of Data from Sensor to User:

6. The LM35 sensor continuously measures the ambient temperature and outputs an analog voltage (10mV per °C) to Arduino's analog pin A0.
7. Arduino reads this analog voltage using analogRead(A0), which returns a value from 0 to 1023 using the built-in 10-bit ADC.
8. Arduino converts the ADC reading to Celsius: Temperature (°C) = (ADC_value × 5000) / (1024 × 10).
9. Arduino checks if the temperature exceeds a defined threshold (e.g., 40°C). If yes, it activates a local buzzer or LED alert.
10. Arduino sends the temperature value to the ESP8266 Wi-Fi module via serial (UART) communication.
11. ESP8266 connects to the Wi-Fi network and makes an HTTP POST request to upload the temperature data to a cloud platform like ThingSpeak.
12. The cloud platform stores the data and generates real-time graphs and historical charts.
13. The user can view the current temperature and historical trends from a smartphone app or web browser from anywhere in the world.

Q9. [8 Marks] **Compare Arduino (AVR) and Raspberry Pi (ARM) regarding architecture, power consumption, and suitable use cases.**

Introduction:

Arduino and Raspberry Pi are the two most popular hardware platforms used in IoT projects. Both are open-source and widely used in education, prototyping, and real projects. However, they are fundamentally different in architecture and capability. Choosing the right platform depends on the nature of the IoT application — simple or complex, real-time or non-real-time.

Feature	Arduino (AVR — ATmega328P)	Raspberry Pi (ARM Cortex-A)
Type	Microcontroller Board	Microcomputer (Single Board Computer)
Processor	ATmega328P — 8-bit AVR RISC	ARM Cortex-A series — 32/64-bit
Clock Speed	16 MHz	1.2 GHz to 1.5 GHz
RAM	2 KB SRAM	1 GB to 8 GB RAM
Storage	32 KB Flash (program memory) + 1 KB EEPROM	MicroSD card (external, expandable)
Operating System	No OS — bare metal programming	Raspberry Pi OS (Linux-based, Debian)
Programming Language	C/C++ (Arduino IDE)	Python, C/C++, Java, Scratch and more
Power Consumption	Very low (~0.2W active, ~20mA)	Moderate to high (~3W–7W depending on load)
Real-Time Performance	Yes — single task, deterministic timing	No — OS scheduling introduces timing jitter
Multitasking	No — runs one loop continuously	Yes — runs multiple processes simultaneously
GPIO Pins	14 digital, 6 analog input	40 GPIO pins (all digital)
Built-in ADC	Yes — 10-bit, 6 channels	No built-in ADC — needs external ADC
Connectivity	Serial, I2C, SPI (no built-in Wi-Fi on Uno)	HDMI, USB, Ethernet, Wi-Fi, Bluetooth
Cost	Low (Arduino Uno ~$10–$25)	Higher (Raspberry Pi 4 ~$35–$75)
Best For	Simple sensor control, timing-critical tasks, motor control	Complex apps, AI/ML, web server, data processing

Architecture Comparison:

Arduino uses the ATmega328P — an 8-bit AVR RISC microcontroller. It has everything on one chip: CPU, Flash, SRAM, EEPROM, and GPIO. It is designed for direct, bare-metal hardware control with deterministic real-time behavior. Raspberry Pi uses an ARM Cortex-A processor — a full multi-core processor similar to what is found in smartphones. It requires a microSD card with an OS installed and has significantly more computing power.

Power Consumption:

Arduino consumes very little power (about 20mA at 5V = 0.1W) making it ideal for battery-powered IoT devices. Raspberry Pi consumes significantly more (typically 700mA–2A at 5V = 3.5W–10W) and requires a stable power supply. This makes Raspberry Pi unsuitable for battery-operated deployments.

Suitable Use Cases:

- Arduino — Simple Projects: Blinking LED, temperature sensor logging, motor control, smart irrigation. Complex Projects: Home automation node, robotics controller, industrial sensor interface.
- Raspberry Pi — Simple Projects: Media center, retro gaming console, file server. Complex Projects: AI and Machine Learning at the edge, home automation hub, web server, industrial HMI, drone controller.

In many real IoT systems, both platforms are used together: Arduino handles real-time sensor reading and control at the device level, while Raspberry Pi acts as the local fog node to aggregate, process, and forward data to the cloud.

UNIT 3 — Protocols for IoT

Q1. [8 Marks] Explain Protocols for IoT.

Introduction:

Protocols in IoT are standardized rules and conventions that define how data is formatted, transmitted, received, and interpreted between IoT devices, gateways, and cloud platforms. Without protocols, devices from different manufacturers would not be able to communicate with each other. IoT protocols can be classified into two main categories: Messaging Protocols (which define how messages are structured and delivered at the application level) and Transport Protocols (which define how data is reliably transmitted across the network).

Why Protocols are Important in IoT:

- IoT devices have very limited resources — small memory, low CPU, and low power. Protocols need to be lightweight and efficient.
- IoT networks are often unreliable (wireless, intermittent connectivity). Protocols must handle dropped connections gracefully.
- IoT deployments are massive in scale — millions of devices. Protocols must be scalable.
- IoT data can be time-sensitive. Some protocols prioritize low latency over reliability.

Messaging Protocols:

MQTT (Message Queuing Telemetry Transport): MQTT is the most widely used IoT messaging protocol. It uses a Publish/Subscribe model where devices (publishers) send messages to a central broker, and other devices (subscribers) receive messages from the broker based on topics they have subscribed to. MQTT runs on TCP and supports three QoS (Quality of Service) levels: 0 (at most once — fire and forget), 1 (at least once — guaranteed delivery but possible duplicates), and 2 (exactly once — guaranteed unique delivery). It is ideal for remote IoT monitoring where bandwidth is limited.

CoAP (Constrained Application Protocol): CoAP is designed specifically for constrained IoT devices with limited RAM and CPU. It uses UDP instead of TCP, making it very lightweight. It supports RESTful interactions (GET, POST, PUT, DELETE) similar to HTTP, and can be easily translated to HTTP for integration with web services. CoAP is ideal for very small IoT sensors.

AMQP (Advanced Message Queuing Protocol): AMQP is an enterprise-grade messaging protocol with support for message queuing, routing, reliability, and security. It is less common in resource-constrained IoT but is useful in industrial IoT where reliability is critical.

XMPP (Extensible Messaging and Presence Protocol): Originally designed for instant messaging, XMPP uses XML-based messages. It has been extended for IoT applications and provides secure, reliable communication.

Transport Protocols:

TCP (Transmission Control Protocol): TCP is a connection-oriented protocol that provides reliable, ordered, and error-checked delivery of data. It uses a 3-way handshake (SYN, SYN-ACK, ACK) to establish connections and acknowledges every packet received. TCP is used when data accuracy is more important than speed — like firmware updates or configuration commands.

UDP (User Datagram Protocol): UDP is connectionless and lightweight. It sends data without establishing a connection and without waiting for acknowledgments. This makes it very fast but unreliable. UDP is used for time-sensitive IoT applications like real-time sensor streaming or video surveillance where a missed packet is better than a delayed one.

DTLS (Datagram Transport Layer Security): DTLS is TLS adapted for UDP. It provides encryption, authentication, and data integrity for UDP-based IoT communication in constrained environments.

Q2. [8 Marks] What is a Protocol? Explain Messaging Protocols in IoT.

What is a Protocol?

A protocol is a set of standardized rules and conventions that govern how data is formatted, transmitted, and received between two or more communicating entities. In networking and IoT, protocols ensure that devices from different manufacturers and running different software can communicate with each other in a predictable and reliable manner. Without protocols, communication would be like two people speaking completely different languages — no information would be exchanged successfully.

In IoT, protocols exist at different layers: some handle hardware-level communication (SPI, I2C), some handle network-level routing (IP), some handle transport-level reliability (TCP, UDP), and some handle application-level messaging (MQTT, CoAP). Messaging protocols are the application-level protocols — they define how IoT devices format and exchange messages.

Messaging Protocols in Detail:

1. MQTT (Message Queuing Telemetry Transport):

MQTT was originally developed by IBM for monitoring oil pipelines via satellite. Today it is the standard messaging protocol for IoT. It uses a Publish-Subscribe model, which is fundamentally different from the traditional request-response model used in HTTP.

In MQTT: Publishers (IoT devices) send messages to a central server called the Broker on a specific topic (e.g., home/temperature). Subscribers (other devices or applications) tell the broker which topics they are interested in and receive messages whenever a publisher sends data on that topic.

- Runs on TCP — ensuring reliable delivery.
- QoS Level 0 — At most once (fire and forget, no acknowledgment).
- QoS Level 1 — At least once (guaranteed delivery, possible duplicates).
- QoS Level 2 — Exactly once (guaranteed unique delivery, highest overhead).
- Very small code footprint — suitable for microcontrollers.
- Best for: Remote monitoring, smart home, industrial IoT.

2. CoAP (Constrained Application Protocol):

CoAP is designed for use with constrained IoT nodes — devices with very limited memory (as little as 10KB) and CPU power. It is similar to HTTP in that it uses a request-response model and supports RESTful operations (GET, POST, PUT, DELETE). Key differences from HTTP: CoAP uses UDP instead of TCP (much lower overhead), has a tiny message format (as small as 4 bytes header), and supports an 'Observe' mode where a client can subscribe to resource updates.

- Runs on UDP — extremely low overhead.
- Can be translated to HTTP easily for web integration.
- Best for: Tiny constrained sensors with very limited resources.

3. AMQP (Advanced Message Queuing Protocol):

AMQP is an open standard application layer protocol for message-oriented middleware. It provides message orientation, queuing, routing, reliability, and security. It is robust but heavier than MQTT and CoAP. Best suited for enterprise IoT and industrial applications where reliability and message queuing are critical. Less common in resource-constrained IoT environments.

4. XMPP (Extensible Messaging and Presence Protocol):

XMPP is an XML-based protocol originally designed for instant messaging (used by Google Talk). It has been extended for IoT applications through standards like XMPP IoT. Key features include decentralized architecture, strong security (TLS), and real-time communication. It is more complex and has higher overhead than MQTT, but offers rich features for presence detection and bidirectional communication.

Protocol	Model	Transport	Overhead	Best For
MQTT	Publish/Subscribe	TCP	Low	Remote IoT monitoring, smart home
CoAP	Request/Response	UDP	Very Low	Tiny constrained devices
AMQP	Message Queue	TCP	High	Enterprise/industrial IoT
XMPP	Message passing	TCP	High	Presence detection, bidirectional comms

---

Q3. [8 Marks] **Explain Transport Protocols in IoT.**

Introduction:

Transport protocols in IoT define the rules for how data is transmitted between two devices or between a device and a server across a network. They operate at the transport layer of the network model and are responsible for ensuring that data arrives correctly, in the right order, and without corruption. In IoT, the three main transport protocols are TCP, UDP, and DTLS. The choice of protocol depends on the application's requirements for reliability, speed, and security.

1. TCP — Transmission Control Protocol:

TCP is a connection-oriented transport protocol. This means before any data can be sent, a connection must be established between the sender and receiver using a 3-way handshake: SYN (sender initiates), SYN-ACK (receiver acknowledges), ACK (sender confirms). Once connected, TCP provides the following guarantees:

- Reliable Delivery — Every packet sent is acknowledged. If an acknowledgment is not received within a timeout, the packet is retransmitted automatically.
- Ordered Delivery — TCP ensures packets arrive in the same order they were sent, even if they travel different routes.
- Error Checking — Every TCP segment includes a checksum for error detection.
- Flow Control — TCP prevents a fast sender from overwhelming a slow receiver.

TCP is used in IoT when data accuracy is more important than speed — such as sending configuration commands, firmware updates, or critical sensor readings that cannot be lost or corrupted. Protocols like MQTT and HTTP run on top of TCP.

Disadvantage: TCP's reliability mechanisms (handshake, acknowledgments, retransmissions) add latency and overhead. This makes TCP unsuitable for real-time or battery-sensitive IoT applications.

2. UDP — User Datagram Protocol:

UDP is a connectionless transport protocol. This means it simply sends data without first establishing a connection and without waiting for acknowledgments. UDP is often described as 'fire-and-forget' — it sends the packet and moves on.

- No connection setup — data is sent immediately.
- No acknowledgment — sender doesn't know if the packet arrived.
- No ordering guarantee — packets may arrive out of order.
- Very low overhead — smaller headers than TCP, less processing.
- Very low latency — no waiting for acknowledgments.

UDP is used in IoT for time-sensitive applications where a missed packet is acceptable but delay is not — such as real-time video streaming, audio streaming, live sensor data feeds, and battery-operated sensors that need to minimize processing. CoAP runs on top of UDP.

Disadvantage: Unreliable — no guarantee of delivery, ordering, or duplicate protection.

3. DTLS — Datagram Transport Layer Security:

DTLS (Datagram Transport Layer Security) is a security protocol that provides the same security guarantees as TLS (Transport Layer Security) — which protects HTTPS web traffic — but adapted to

work over UDP. Since UDP is connectionless and unreliable, TLS cannot work directly over UDP (TLS requires reliable ordered delivery). DTLS adds its own reliability mechanisms to make TLS work over UDP.

DTLS provides: Confidentiality (data is encrypted so eavesdroppers cannot read it), Integrity (data cannot be modified in transit without detection), and Authentication (both client and server can verify each other's identity using certificates).

DTLS is critical in IoT because many IoT devices use UDP-based protocols like CoAP (which has no built-in security). Adding DTLS to CoAP (CoAPs = CoAP over DTLS) provides the security needed for sensitive IoT applications like healthcare monitoring or industrial control.

Q4. [8 Marks] Write a short note on IPv4.

Introduction:

IPv4 (Internet Protocol version 4) is the fourth version of the Internet Protocol and the most widely deployed network layer protocol in the world. It defines the addressing system that assigns unique numerical identifiers (IP addresses) to every device connected to the internet, enabling data packets to be routed from source to destination across networks. IPv4 was introduced in 1981 and has been the foundation of the internet for over four decades.

IPv4 Address Format:

An IPv4 address is a 32-bit number written in dotted-decimal notation — four groups of 8-bit numbers (octets) separated by dots. Each octet can range from 0 to 255. Example: 192.168.1.100. With 32 bits, the total number of possible IPv4 addresses is 2^32 = approximately 4.3 billion unique addresses.

Key Features of IPv4:

- 32-bit address space — approximately 4.3 billion unique addresses.
- Dotted-decimal notation — e.g., 192.168.1.1.
- Connectionless protocol — each packet is independently routed.
- Best-effort delivery — does not guarantee delivery, ordering, or error recovery (relies on transport layer protocols like TCP for this).
- Supports unicast (one-to-one), broadcast (one-to-all), and multicast (one-to-group) addressing.

IPv4 Address Classes:

Class	Range	Purpose
A	0.0.0.0 – 127.255.255.255	Large networks (e.g., ISPs, large enterprises)
B	128.0.0.0 – 191.255.255.255	Medium-sized networks
C	192.0.0.0 – 223.255.255.255	Small networks (most common)
D	224.0.0.0 – 239.255.255.255	Multicast
E	240.0.0.0 – 255.255.255.255	Reserved/Experimental

IPv4 Limitations in IoT:

The biggest limitation of IPv4 in the context of IoT is address exhaustion. With approximately 4.3 billion addresses and over 15 billion IoT devices currently deployed (expected to grow to 30+ billion), IPv4 simply cannot provide a unique public IP address for every IoT device. This has forced the use of NAT (Network Address Translation), which allows multiple devices to share a single public IP address. While NAT temporarily solved the address shortage, it complicates direct device-to-device communication and increases latency — problems that are significant in IoT. Security in IPv4 is optional (IPsec is available but not mandatory). This is another limitation in the security-sensitive IoT environment.

Q5. **[8 Marks]** **Write a short note on IPv6.**

Introduction:

IPv6 (Internet Protocol version 6) is the successor to IPv4 and was developed by the Internet Engineering Task Force (IETF) to address the critical limitations of IPv4 — primarily address exhaustion. IPv6 was formally introduced in 1998 and has been gradually adopted alongside IPv4. For IoT, IPv6 is not just an upgrade — it is an essential requirement because the number of IoT devices far exceeds the available IPv4 address space.

IPv6 Address Format:

An IPv6 address is a 128-bit number written in hexadecimal, divided into 8 groups of 16-bit segments separated by colons. Example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334. With 128 bits, IPv6 can provide 2^128 = approximately 340 undecillion (3.4 × 10^38) unique addresses — practically infinite compared to IPv4.

Key Features of IPv6:

- 128-bit address space — effectively unlimited addresses. Every IoT device can get a unique global IP address.
- Hexadecimal notation — example: 2001:db8::1.
- No NAT required — every device can have a unique public IP, enabling true end-to-end connectivity.
- Built-in IPsec — security (encryption and authentication) is mandatory in IPv6, not optional like in IPv4.
- Stateless Address Auto-configuration (SLAAC) — IoT devices can automatically configure their own IPv6 address without a DHCP server.
- Improved routing — simplified packet headers reduce router processing overhead.
- Better support for multicast and no broadcast — reduces unnecessary network traffic.

IPv6 and IoT — Why It Matters:

IoT is driving IPv6 adoption at an unprecedented rate. Consider this: a single smart factory with thousands of sensors, actuators, cameras, and controllers would easily exhaust multiple IPv4 address blocks. With IPv6, every single IoT device — from a tiny soil moisture sensor to an industrial robot — can have its own unique, globally routable IP address. This enables: direct device-to-device communication without NAT, easier remote access to individual devices, simpler network management, and better integration with cloud platforms.

6LoWPAN — IPv6 for Constrained IoT Devices:

One challenge with IPv6 is that its header is large (40 bytes) compared to IPv4 (20 bytes). For very constrained IoT devices using low-power radio protocols like Zigbee or IEEE 802.15.4, even 40 bytes is too large. 6LoWPAN (IPv6 over Low-Power Wireless Personal Area Networks) solves this by compressing IPv6 headers to as few as 2 bytes, making it possible to run IPv6 on tiny IoT devices with very limited bandwidth.

Q6. [4 Marks] Difference between IPv4 and IPv6.

Feature	IPv4	IPv6
Address Size	32-bit	128-bit
Total Addresses	~4.3 billion (2^32)	~340 undecillion (2^128)
Notation	Dotted-decimal (192.168.1.1)	Hexadecimal with colons (2001:db8::1)
NAT Requirement	Yes — needed due to address shortage	No — every device gets unique global IP
Security (IPsec)	Optional — not built into the protocol	Mandatory — built-in by default
Header Size	20 bytes (variable)	40 bytes (fixed, simpler)
Configuration	Manual or DHCP required	Auto-configuration via SLAAC possible
Broadcast	Supports broadcast	No broadcast — uses multicast instead
Fragmentation	Done by routers and sender	Done only by the sender
Checksum	Header checksum present	No header checksum (handled by transport layer)
IoT Suitability	Limited — address exhaustion is a major problem	Essential — each IoT device gets unique IP
Adoption	Widely deployed, mature ecosystem	Growing rapidly, especially in IoT and mobile

In summary, IPv6 was designed to overcome IPv4's limitations. For IoT specifically, IPv6 is critical because IoT deployments involve billions of devices that all need unique network identities. IPv4's address space simply cannot support this scale.

Q7. [4 Marks] Explain IEEE 802.15.4.

Introduction:

IEEE 802.15.4 is a technical standard developed by the IEEE (Institute of Electrical and Electronics Engineers) that defines the Physical (PHY) layer and Media Access Control (MAC) layer specifications for low-rate wireless personal area networks (LR-WPANs). It is the foundational wireless communication standard specifically designed for low-power, low-data-rate IoT and embedded system applications. Many popular IoT wireless technologies like Zigbee, Thread, and 6LoWPAN are built on top of IEEE 802.15.4.

Key Features of IEEE 802.15.4:

- Low Power Consumption — designed for battery-operated devices that need to last months or years. Devices can operate in sleep mode most of the time and wake up only to transmit data.
- Low Data Rate — supports data rates of 250 kbps (at 2.4 GHz band), 40 kbps (915 MHz), and 20 kbps (868 MHz). This is much lower than Wi-Fi but sufficient for small sensor data.
- Short Range — typical range is 10–100 meters in indoor environments. Range can be extended using mesh networking.
- Star and Peer-to-Peer Topologies — supports simple star topology (all devices connect to one coordinator) and peer-to-peer topology (mesh networking where devices relay each other's messages).

- Frequency Bands — operates in 2.4 GHz (globally), 915 MHz (Americas), and 868 MHz (Europe).
- 16 channels in the 2.4 GHz band, 10 channels in 915 MHz, 1 channel in 868 MHz.

Device Types in IEEE 802.15.4:

- FFD (Full Function Device) — can act as coordinator or router. Can communicate with any other device. Example: Zigbee coordinator.
- RFD (Reduced Function Device) — simplified device that can only communicate with FFDs. Designed for maximum power savings. Example: simple end sensor node.

Applications of IEEE 802.15.4 in IoT:

- Wireless sensor networks for industrial monitoring.
- Smart home automation (via Zigbee protocol built on 802.15.4).
- Medical body sensor networks.
- Agricultural monitoring — soil sensors communicating over 802.15.4.
- Smart metering for electricity and gas.

UNIT 4 — Cloud for IoT

Q1. **[8 Marks]** **Write a short note on Cloud for IoT.**

Introduction:

Cloud computing and IoT are two of the most transformative technologies of the modern era, and together they form a powerful combination that enables truly scalable, intelligent, and accessible IoT systems. Cloud for IoT refers to the use of cloud computing infrastructure — including storage, processing, analytics, and platform services — to support the collection, management, and analysis of data generated by millions of IoT devices. Without cloud computing, IoT at scale would simply not be possible.

Why IoT Needs Cloud:

IoT devices generate enormous volumes of data continuously. A single smart factory with thousands of sensors can generate gigabytes of data per day. It is not practical to store and process this data on the IoT devices themselves (they have very limited memory and processing power). Cloud platforms provide virtually unlimited storage and elastic computing resources that can scale up or down based on demand.

Key Benefits of Cloud for IoT:

- Data Storage and Processing: Cloud provides scalable storage solutions for IoT data. Platforms like AWS IoT Core, Microsoft Azure IoT Hub, and Google Cloud IoT store sensor data reliably and make it available for analysis.
- Scalability: Cloud platforms can dynamically scale their resources to handle the increasing amount of data as more IoT devices are added to the network. No hardware upgrades needed at the user's end.
- Data Analytics: Cloud platforms provide advanced analytics and machine learning services that can process IoT data to generate insights, detect patterns, and make predictions. For example, AWS Machine Learning can analyze temperature trends from thousands of sensors and predict equipment failure.
- Accessibility: Cloud services can be accessed from anywhere in the world. A user can monitor and control their IoT devices remotely from a smartphone app connected to the cloud platform.
- Cost Efficiency: Pay-as-you-go pricing models eliminate the need for significant upfront capital expenditure on hardware. Users only pay for the storage and computing they actually use.

Cloud Service Models for IoT:

- IaaS (Infrastructure as a Service) — provides virtual machines, storage, and networking. User manages OS and applications. Example: AWS EC2. Best for custom IoT backends.
- PaaS (Platform as a Service) — provides development and deployment platforms. User builds and manages applications. Example: AWS Lambda. Best for building IoT applications.
- SaaS (Software as a Service) — complete software delivered to user. Example: ThingSpeak for IoT data visualization. Best for quick deployment.

Cloud Deployment Models for IoT:

- Private Cloud — for organizations with strict security requirements. High control but expensive.
- Public Cloud — most common for IoT. Cost-effective and scalable.
- Hybrid Cloud — mix of private and public. Sensitive data on private cloud, bulk storage on public.

Q2. [8 Marks] Explain IoT and Cloud.

Introduction:

The integration of IoT and cloud computing is one of the most significant developments in modern technology. IoT generates data at an unprecedented scale through millions of connected sensors and devices. Cloud computing provides the infrastructure, tools, and services needed to store, process, and derive insights from this data. Together, they enable intelligent, scalable, and remotely accessible systems that are transforming industries from healthcare to agriculture to manufacturing.

How IoT and Cloud Work Together:

In a typical IoT-cloud system, the data flow works as follows: IoT sensors collect data from the physical environment. A local controller (like Arduino or Raspberry Pi) processes this data and sends it to the cloud via the internet using a communication protocol like MQTT or HTTP. The cloud platform receives the data, stores it, runs analytics (sometimes using AI/ML), and presents insights through dashboards or APIs that users can access from any device.

Key Integration Points:

- Data Storage and Management: Cloud provides persistent, scalable storage for IoT time-series data. Services like AWS DynamoDB, Azure Cosmos DB, and Google Bigtable are optimized for IoT data patterns.
- Real-time Processing: Cloud services like AWS Kinesis and Azure Stream Analytics process IoT data streams in real-time, enabling immediate responses to events.
- Machine Learning at Cloud: Cloud ML services analyze historical IoT data to build predictive models — for example, predicting machine failures in industrial IoT.
- Device Management: Cloud platforms provide IoT device management services — handling device registration, authentication, firmware updates, and monitoring the health of thousands of devices.
- Remote Control: Through the cloud, users can send commands to IoT devices from anywhere — for example, turning on a smart light or adjusting a thermostat remotely.

IoT Cloud Use Cases:

- Smart Homes: Smart thermostats, lighting, and security systems use cloud for data processing and remote control via smartphone apps.
- Healthcare: Wearable devices monitor patient vitals and send data to the cloud for real-time analysis and doctor access.
- Industrial IoT: Sensors in manufacturing plants collect data for predictive maintenance and operational efficiency via cloud analytics.
- Agriculture: Soil sensors send moisture and nutrient data to the cloud, which analyzes it and sends irrigation commands back to the field.

Challenges of IoT-Cloud Integration:

- Privacy and Security — sensitive IoT data must be protected in transit and at rest.
- Bandwidth and Latency — sending all IoT data to the cloud requires significant bandwidth and can introduce latency.

- Data Ownership — data stored with a cloud service provider raises questions about who owns the data.
- Cost — cloud storage and computing costs increase as IoT data volumes grow.

Q3. [8 Marks] Explain Fog Computing.

Introduction:

Fog computing is an extension of cloud computing that brings data processing, storage, and services closer to the source of data — the IoT devices at the network edge. Instead of sending all IoT data to a distant cloud server for processing, fog computing introduces intermediate processing nodes (called fog nodes) between the IoT devices and the cloud. These fog nodes are typically located on the Local Area Network (LAN) near the IoT devices — for example, a Raspberry Pi or a local server in the same building as the sensors.

The term 'Fog' was coined by Cisco to describe this intermediate layer that sits between the IoT devices (at the bottom) and the cloud (at the top). Just as fog is low-lying cloud, fog computing is 'cloud brought down closer to the ground.'

Why Fog Computing is Needed:

Many IoT applications require real-time or near-real-time responses. If every piece of data has to travel to a distant cloud server and back before action is taken, the latency can be hundreds of milliseconds — unacceptable for applications like autonomous vehicles, industrial robot control, or emergency healthcare monitoring. Additionally, sending all raw sensor data to the cloud consumes enormous bandwidth and increases costs.

Architecture: Edge → Fog → Cloud

- Edge (Device Layer): IoT sensors and actuators collect raw data. Arduino, ESP8266 collect sensor readings.
- Fog Layer (Local Processing): Fog nodes (Raspberry Pi, local server) receive raw data from sensors. They perform: filtering (remove noise and irrelevant data), aggregation (combine data from multiple sensors), analysis (run algorithms to detect events), local alerts (send immediate alerts to local team), and data reduction (send only summarized/filtered data to cloud to save bandwidth).
- Cloud Layer: Receives summarized/filtered data from fog. Performs long-term storage, deep analytics, machine learning, and provides global access dashboards.

Key Characteristics of Fog Computing:

- Proximity to End Devices: Fog nodes are physically close to IoT devices, reducing network latency from hundreds of milliseconds (cloud) to single-digit milliseconds.
- Real-time Processing: Capable of processing time-sensitive data immediately at the local level.
- Reduced Bandwidth: Only important/summarized data is sent to the cloud — not all raw data. This significantly reduces bandwidth costs.
- Improved Security: Sensitive data can be processed locally without having to travel over the internet to the cloud.
- Offline Operation: Fog nodes can continue working even when internet connectivity to the cloud is lost.

Fog Computing vs Edge Computing:

Edge computing processes data directly at the IoT device itself (or at a device immediately adjacent to the sensor). Fog computing processes data at a LAN-connected node — slightly further from the sensor than edge, but much closer than cloud. Edge is on the device; fog is on the local network.

Use Cases of Fog Computing:

- Smart Cities: Real-time traffic signal control, surveillance systems processing video locally.
- Industrial Automation: Fog node processes robot sensor data locally for real-time control.
- Healthcare: Fog node analyzes patient vital signs locally for immediate alerts.
- Oil and Gas: Fog nodes at remote drilling sites analyze sensor data locally.

Q4. [4 Marks] Difference between IoT and Cloud.

Feature	IoT (Internet of Things)	Cloud Computing
Definition	Network of physical devices connected over the internet to collect and exchange data	Delivery of computing services (storage, servers, databases, networking, analytics) over the internet
Primary Function	Sense, collect, and communicate real-world data	Store, process, and analyze data at scale
Physical Presence	Has physical hardware — sensors, actuators, controllers deployed in the real world	Purely virtual/software — no physical presence for the user
Data Generation	Generates data through sensors and devices	Receives, stores, and processes data generated by IoT and other sources
Processing Location	Limited processing at the device level	Massive processing power in data centers
Connectivity	Devices connect to each other and to the cloud	Cloud connects to devices and to the internet
Examples	Smart thermostat, wearable fitness band, industrial sensor	AWS IoT Core, Azure IoT Hub, Google Cloud IoT
Without Each Other	IoT without cloud has limited storage and analytics capability	Cloud without IoT has no real-world data source for many use cases
Relationship	IoT generates data that cloud processes and stores	Cloud provides the backend infrastructure for IoT systems

In practice, IoT and cloud are not competing technologies — they are complementary. IoT is the data source (the front end of the system) and cloud is the data brain (the back end). Together they form a complete system for sensing, storing, analyzing, and acting on real-world data.

Q5. [4 Marks] Write a short note on Security in Cloud for IoT.

Introduction:

Security in cloud computing for IoT refers to the set of measures, practices, and technologies used to protect IoT data, devices, and cloud infrastructure from unauthorized access, cyberattacks, data breaches, and misuse. When IoT devices send sensitive data to cloud platforms — such as health readings, location data, or industrial control signals — ensuring the security of this data throughout its lifecycle (from the device to the cloud) is absolutely critical.

Key Security Concerns:

- Data Security: Protecting data at rest (stored in cloud), in transit (traveling from IoT device to cloud over the internet), and in use (being processed).
- Authentication and Authorization: Ensuring that only legitimate IoT devices and authorized users can access cloud services and data.
- Device Security: Ensuring that the IoT devices themselves are not compromised and used as entry points to attack the cloud.
- Network Security: Protecting data as it travels between IoT devices and the cloud over potentially insecure networks.

Security Threats in IoT Cloud:

- Data Breaches: Unauthorized access to sensitive IoT data stored in cloud.
- Insecure APIs: Cloud APIs used by IoT devices can be exploited if poorly secured.
- Man-in-the-Middle Attacks: Interception of data between IoT device and cloud if communication is not encrypted.
- Regulatory Compliance: Failing to meet data protection regulations (GDPR, HIPAA) when storing personal IoT data in cloud.

Security Best Practices:

- Data Encryption: Encrypt all data in transit (using TLS/DTLS) and at rest (using AES-256 or similar).
- Strong Authentication: Implement multi-factor authentication (MFA) for user access and certificate-based authentication for IoT devices.
- Regular Security Audits: Conduct periodic vulnerability assessments and penetration testing.
- Patch Management: Regularly update and patch IoT device firmware and cloud services.
- Strict Access Controls: Implement role-based access control (RBAC) to limit what each user and device can access.
- Anti-malware and Monitoring: Use cloud security services for real-time threat detection and response.

UNIT 5 — Application Building with IoT

Q1. [4 Marks] **Write the various applications of IoT.**

Introduction:

IoT applications span across virtually every industry and domain. The common architecture for all IoT applications follows this template: Sensor Nodes → Controller Node → Fog/Local Computer → Cloud → Remote Monitoring. Each application adapts this template with specific sensors, controllers, and business logic. Below are the key application areas of IoT:

- Food and Agriculture: Smart agriculture uses soil moisture sensors, nutrient sensors, and weather monitoring to optimize crop yields. Food safety systems track temperature and humidity during storage and transport to prevent spoilage.
- Healthcare: Wearable devices monitor heart rate, blood pressure, oxygen levels, and glucose continuously. Smart hospitals track medical equipment and patient conditions in real-time.
- Lavatory Maintenance: Smart restrooms use sensors to monitor supply levels, toilet usage, and cleanliness. Predictive maintenance alerts staff about leaks or malfunctions.
- Water Quality Monitoring: IoT sensors measure pH, turbidity, temperature, dissolved oxygen, and contaminants in water bodies. Unmanned Surface Vehicles (USVs) carry sensor packages across water bodies.
- Warehouse Management: RFID tags and IoT sensors track inventory levels and movement. IoT-enabled robots and AGVs automate picking and packing.
- Retail: Smart shelves detect product levels. Beacons track customer movement. RFID enables automated billing at exit.
- Driver Assistance: Cameras, OBD modules, and ultrasonic sensors monitor driver behavior and road conditions. ADAS provides lane departure warnings, drowsiness alerts, and adaptive cruise control.
- Collision Impact Detection: FSR sensors detect impact severity. GPS provides location. System automatically alerts emergency services with location, severity, fire status, and passenger count.
- Smart Cities: Traffic management, energy optimization, waste management, and public safety systems.

Q2. [8 Marks] **Explain the following applications of IoT: Food and Healthcare.**

A. Food / Agriculture IoT

Introduction:

The food and agriculture industry is one of the most impactful application areas of IoT. Traditional farming relies on manual observation and fixed schedules for irrigation and fertilization — processes that are inefficient and often waste resources. IoT-based precision agriculture and food safety systems use real-time sensor data to make farming smarter, more efficient, and more sustainable.

1. Smart Agriculture:

In smart agriculture, IoT sensors are deployed across farmland to continuously monitor key parameters: soil moisture sensors check if the soil has adequate water content, nutrient sensors measure nitrogen, phosphorus, and potassium levels, and weather stations collect temperature, humidity, and rainfall data. This data is sent to a cloud platform where it is analyzed. When soil moisture drops below a threshold, the system automatically activates drip irrigation. When nutrient levels are low, the system schedules fertilizer application. This precision approach prevents over-watering and over-fertilizing — saving water, reducing costs, and improving yield quality.

- Drones equipped with cameras and sensors scan large agricultural areas, identifying crop diseases, pest infestations, and areas needing attention.
- Automated farming machinery uses GPS and IoT to follow precise planting and harvesting patterns.

2. Food Safety — Cold Chain Monitoring:

Maintaining food safety during storage and transportation is critical. Perishable foods like meat, dairy, and produce must be kept within specific temperature ranges. IoT temperature and humidity sensors are placed inside refrigerators, trucks, and warehouses. These sensors continuously monitor conditions and send real-time alerts if temperature deviates from the safe range. If a refrigeration unit fails during transport, the logistics team receives an immediate alert and can take corrective action before the food spoils. This prevents food waste and protects consumers from foodborne illness.

B. Healthcare IoT

Introduction:

Healthcare IoT is one of the most life-critical application areas. IoT in healthcare reduces hospital stays, enables remote monitoring, prevents medical emergencies, and improves overall patient outcomes. The IoT healthcare architecture typically involves wearable or bedside sensor devices → a local controller node (NodeMCU or Arduino) → a fog node (Raspberry Pi) → cloud platform → remote access by doctors, family, and analytics systems.

1. Remote Patient Monitoring:

Wearable IoT devices are worn by patients and continuously measure vital signs like heart rate, blood pressure, oxygen saturation (SpO2), body temperature, and glucose levels. This data is sent in real-time to the cloud. Doctors can monitor multiple patients remotely from a dashboard without requiring them to be physically present in the hospital. If any vital sign goes outside the safe range, the system immediately sends an alert to the duty nurse, the doctor, and the patient's family. This is especially valuable for chronic disease patients who need continuous monitoring.

2. Smart Hospitals:

In a smart hospital, IoT devices track the location of all medical equipment (infusion pumps, wheelchairs, defibrillators) in real-time using RFID and Bluetooth beacons. This eliminates the time wasted searching for equipment during emergencies. IoT also monitors environmental conditions like temperature and humidity in operation theatres and medicine storage areas to ensure they stay within required ranges.

3. Medication Management:

Smart pill dispensers are IoT devices that store a patient's daily medication and dispense the correct pills at the correct times based on the prescribed schedule. If a dose is missed, the dispenser sends

an alert to the patient's smartphone and to the caregiver. This is particularly valuable for elderly patients living alone who may forget to take critical medications.

Q3. [8 Marks] Explain the following applications of IoT: Water Quality and Retail.

A. Water Quality Monitoring IoT

Introduction:

Access to clean water is a fundamental human right, yet water contamination remains a critical global problem. Traditional water quality testing requires collecting water samples manually and sending them to a laboratory — a process that is time-consuming, expensive, and not real-time. IoT-based water quality monitoring systems overcome these limitations by continuously measuring water quality parameters in-situ (at the actual location) and sending data to the cloud in real-time.

System Architecture:

Sensors are mounted on an USV (Unmanned Surface Vehicle) — a small boat-like robot that navigates across a water body (lake, river, reservoir) collecting measurements at multiple points. This is better than fixed sensor installations because the USV can cover a wide area. Alternatively, fixed sensors are placed at critical points in the water supply network.

Sensors Used:

- pH Sensor — measures acidity/alkalinity of water. Safe drinking water pH: 6.5–8.5.
- Temperature Sensor — measures water temperature which affects dissolved oxygen levels and bacterial growth.
- Conductivity Sensor — measures the ability of water to conduct electricity, indicating dissolved salts and minerals.
- Turbidity Sensor — measures water cloudiness caused by suspended particles.
- Dissolved Oxygen (DO) Sensor — critical for aquatic life and water quality assessment.
- TDS (Total Dissolved Solids) Sensor — measures overall dissolved content.
- GPS Module — records the exact location where each measurement is taken.

Data Flow:

Sensors → Microcontroller → GPRS/GSM module → Internet → Cloud Platform. The cloud analyzes data and generates alerts if any parameter exceeds safe limits. Water utility companies, environmental agencies, and municipalities can access this data from their dashboards. Smart Water Grids detect leaks in the pipe network and send alerts for repair. Flood detection systems use water level sensors to provide early warnings.

Advantages over Manual Testing:

- Real-time monitoring vs periodic lab testing.
- No human error in measurement.
- Continuous data history for trend analysis.
- Cost-effective once deployed.

B. Retail IoT

Introduction:

The retail industry has been significantly transformed by IoT. From inventory management to customer experience to security, IoT enables retailers to operate more efficiently, reduce losses, and provide a better shopping experience. IoT in retail uses a combination of RFID tags, sensors, cameras, and Bluetooth beacons to create a smart retail environment.

Key Retail IoT Applications:

1. RFID-Based Smart Inventory:

Every product in the store has an RFID tag attached to it. RFID readers at various points in the store and at the exit automatically scan all tagged items. The system maintains a real-time inventory count — when stock falls below a threshold, an automatic reorder is placed with the supplier. At the exit,

the RFID reader scans all items in the customer's cart automatically — enabling queue-less self-checkout without requiring items to be taken out and scanned individually.

2. Smart Shelves:

Weight sensors embedded in shelves detect the weight of products on the shelf. When the weight drops below a threshold (indicating low stock), the system sends an alert to store staff to restock that item. This ensures shelves are never empty and customers always find what they're looking for.

3. Customer Analytics using Beacons:

BLE (Bluetooth Low Energy) beacons placed throughout the store detect customers' smartphones and track their movement patterns. This data reveals which areas of the store get the most traffic, which product displays attract the most attention, and where customers tend to linger. Retailers use this information to optimize store layout, product placement, and promotional displays. Beacons also send personalized discount notifications to customers' smartphones based on which section of the store they are in.

4. Automated Safety:

Fire sensors automatically trigger alarms and activate water sprinklers when smoke or heat is detected. Gas sensors detect leaks and trigger emergency protocols — all without human intervention.

Q4. [4 Marks] Explain Driver Assistance application of IoT.

Introduction:

Driver Assistance IoT systems use a combination of cameras, sensors, OBD (On-Board Diagnostics) units, and AI algorithms to continuously monitor both the driver's state and the vehicle's surroundings. The goal is to detect dangerous situations — like driver drowsiness, lane departure, or obstacles — and provide timely warnings or automatic corrective actions to prevent accidents. These systems are the foundation of ADAS (Advanced Driver Assistance Systems) found in modern vehicles.

Hardware Components:

- Camera Units: Mounted inside the vehicle to monitor the driver's face and outside to monitor the road and surroundings.
- OBD Unit (On-Board Diagnostics): Reads vehicle data including speed, acceleration, steering angle, engine RPM, and brake usage.
- Ultrasonic Sensors: Detect nearby objects and obstacles around the vehicle for parking assistance and collision warning.
- GPS Module: Tracks vehicle location and speed in real-time.
- Controller: Raspberry Pi or ARM-based embedded computer processes all sensor data in real-time.

Key Functions:

1. Drowsiness Detection using EAR (Eye Aspect Ratio): The camera monitors the driver's eyes. The EAR (Eye Aspect Ratio) formula is used to determine if the driver is falling asleep. EAR = [(P2–P6) + (P3–P5)] / [2 × (P1–P4)], where P1–P6 are facial landmark points around the eye. When eyes are open, EAR is approximately 0.3. When eyes close (drowsiness), EAR drops toward 0. If EAR stays below a threshold for several consecutive frames, the system triggers an alarm to wake the driver.

2. Lane Departure Warning: The road-facing camera continuously analyzes lane markings. If the vehicle begins to drift out of its lane without the turn signal being activated, the system warns the driver with an audio alert.

3. Collision Avoidance: Ultrasonic sensors detect objects in the vehicle's path. The system warns the driver and can apply automatic emergency braking if a collision is imminent.

4. Fleet Management: All vehicle data (location, speed, driving behavior) is sent to the cloud, allowing fleet managers to monitor all vehicles in real-time, optimize routes, and ensure driver safety compliance.

Q5. [8 Marks] **Explain the following applications of IoT: Warehouse and Collision Impact.**

A. Warehouse Management IoT

Introduction:

Warehouse management is one of the most impactful IoT applications in the logistics and supply chain industry. Traditional warehouses rely on manual processes for inventory tracking, picking, and environmental monitoring — processes that are slow, error-prone, and expensive. IoT-based smart warehouses use RFID tags, sensors, automated robots, and cloud-connected systems to create a highly efficient, accurate, and automated warehouse operation.

Key Components:

- RFID Tags and Readers: Every item in the warehouse has an RFID tag. RFID readers mounted at entry/exit points and on shelving units automatically scan items and update inventory records in real-time. No manual scanning required.
- IoT Sensors: Temperature and humidity sensors monitor environmental conditions — critical for warehouses storing food, pharmaceuticals, or sensitive electronics. If conditions deviate from safe ranges, automatic HVAC adjustments are triggered.
- AGVs (Automated Guided Vehicles): IoT-enabled robotic vehicles navigate the warehouse floor using sensors and maps, picking items from shelves and delivering them to packing stations automatically.
- WMS (Warehouse Management System): Cloud-based software that receives data from all IoT devices, manages inventory records, generates pick lists, and coordinates AGV movements.

Key Benefits:

- Real-time inventory accuracy — eliminates human counting errors.
- Faster order fulfillment — AGVs work 24/7 without breaks.
- Reduced operational costs — fewer human workers for repetitive tasks.
- Proactive maintenance — sensors detect equipment issues before failure.
- Environmental compliance — continuous monitoring ensures goods are stored correctly.

B. Collision Impact Detection IoT

Introduction:

Road accidents are a leading cause of death globally. The critical issue in road accidents is the delay between the crash and the arrival of emergency services — a delay that often means the difference between life and death. An IoT-based Collision Impact Detection system automatically detects when a vehicle has been in a serious accident and immediately alerts relevant emergency services with precise information about the crash, enabling faster response.

Sensors Used:

- FSR (Force Sensitive Resistor): Measures impact force. Mounted at the most vulnerable points of the vehicle (front bumper, side panels). When collision force exceeds a threshold, it confirms a serious crash.
- Fire Sensor: Detects if a fire has broken out after the collision — critical for alerting fire brigade.
- GPS Module: Records the precise location of the vehicle at the time of impact.
- OBD Unit: Records vehicle speed and deceleration data at the moment of impact — useful for accident reconstruction.
- Camera: Estimates number of passengers in the vehicle — helps emergency responders prepare the right resources.

System Operation:

14. FSR sensor detects impact above threshold → triggers the alert system.

15. System collects data from all sensors: GPS location, fire status, speed at impact, passenger count.
16. Alert message is sent immediately via GSM/GPRS to: Ambulance services, Nearest hospital, Highway patrol, Fire brigade (if fire detected), Police, and the driver's registered family contacts.
17. Alert contains: Exact GPS location, Impact severity (from FSR), Fire status (yes/no), Vehicle speed at impact, Estimated passenger count, Time of incident.
18. Emergency services respond with the right resources to the exact location — no time wasted searching for the accident.

Advantages:

- Zero delay in reporting — automatic alert sent within seconds of impact.
- Precise location — GPS eliminates the problem of reporting inaccurate locations.
- Multi-agency alert — all relevant services notified simultaneously.
- Works even if driver is unconscious — fully automatic system.

Q6. [8 Marks] Explain the following applications of IoT: Smart Cities and Smart Grid.

A. Smart Cities IoT

Introduction:

A Smart City uses digital technologies including IoT to improve the quality of life for its residents, enhance the efficiency of city services, and reduce environmental impact. IoT is the foundation of smart city infrastructure — connecting traffic systems, public utilities, emergency services, waste management, and public spaces through a network of sensors and automated systems. The data collected by these sensors is analyzed in real-time to optimize city operations and improve the citizen experience.

Key Smart City IoT Applications:

- Smart Traffic Management: Sensors and cameras at intersections monitor real-time traffic volume. Traffic management system dynamically adjusts signal timings. Emergency vehicle pre-emption clears routes automatically.
- Smart Street Lighting: Light sensors and motion sensors control street lights automatically — lights dim when no one is present and brighten when pedestrians approach. This saves significant energy compared to always-on lighting.
- Smart Waste Management: Fill-level sensors in waste bins alert collection teams only when bins are full, enabling dynamic collection routes that save fuel and reduce collection frequency.
- Air Quality Monitoring: IoT sensors at multiple locations monitor PM2.5, PM10, CO_2, NO_2 levels in real-time. Data drives decisions about vehicle restrictions and industrial activity on high-pollution days.
- Smart Water Supply: Sensors in water pipes detect leaks, monitor pressure, and track flow rates. Automatic alerts enable fast repair before significant water is wasted.
- Public Safety: Smart cameras with AI detect crimes, accidents, and suspicious activities in real-time and alert police.

B. Smart Grid IoT

Introduction:

A Smart Grid is an electricity supply network that uses IoT and digital communication technology to monitor, analyze, and optimize the production, distribution, and consumption of electrical energy. Traditional power grids are one-way systems — power flows from generation plants to consumers. A smart grid is a two-way system where both power and information flow between the utility company and consumers. IoT is the core technology that makes the smart grid possible.

Key Components of Smart Grid IoT:

- Smart Meters: IoT-enabled electricity meters installed at every home and business. They measure power consumption in real-time (rather than monthly readings) and send data to the utility company automatically via wireless communication. Smart meters also enable Time-of-Use pricing — charging different rates at different times of day to encourage off-peak usage.
- Sensors on Power Lines and Substations: IoT sensors monitor voltage, current, temperature, and fault conditions across the grid in real-time. When a fault is detected, the system can automatically reroute power and dispatch repair teams with precise fault location.
- Demand Response Systems: The grid can send signals to smart appliances (like water heaters and air conditioners) to reduce consumption during peak demand periods — preventing blackouts without adding new generation capacity.
- Renewable Energy Integration: Smart grid IoT manages the variable output of solar panels and wind turbines, balancing supply and demand in real-time using energy storage systems.

Benefits of Smart Grid:

- Reduced power outage duration through automatic fault detection and isolation.
- Better integration of renewable energy sources.
- Consumers get detailed insights into their energy consumption.
- Utility companies can balance supply and demand more efficiently.
- Reduced energy waste and lower carbon emissions.

UNIT 6 — Arduino and Raspberry Pi

Q1. **[4 Marks]** **Explain Arduino.**

Introduction:

Arduino is an open-source electronics platform designed for creating interactive projects. It is one of the most widely used microcontroller platforms in IoT, education, robotics, and prototyping. The Arduino platform consists of two main parts: the Arduino hardware board (which is a physical microcontroller circuit board) and the Arduino Software IDE (Integrated Development Environment), which is used to write and upload programs to the board. Arduino was created in Italy in 2005 and has since become the most popular prototyping platform for beginners and professionals alike.

Arduino Uno Architecture:

- Microcontroller: ATmega328P (8-bit AVR RISC processor).
- Clock Speed: 16 MHz.
- Flash Memory: 32 KB (program storage). 0.5 KB used by bootloader.
- SRAM: 2 KB (runtime data storage).
- EEPROM: 1 KB (non-volatile data storage).
- Digital I/O Pins: 14 (of which 6 support PWM output for controlling motor speed, LED brightness, etc.).
- Analog Input Pins: 6 (connected to 10-bit ADC for reading analog sensors).
- Operating Voltage: 5V.
- Power Supply: Via USB or external 7–12V DC.
- Communication: UART (Serial), SPI, I2C built-in.

Programming:

Arduino is programmed using Arduino IDE in a language based on C/C++. Every Arduino program (called a 'sketch') has two main functions: setup() — runs once when the board is powered on or

reset, used to initialize pins and settings; and loop() — runs continuously after setup(), contains the main logic of the program.

Applications:

- Simple: Blinking LED, temperature sensor reading, motor control.
- Complex: Home automation node, robotics, IoT sensor devices, industrial control.

Q2. [4 Marks] Explain Raspberry Pi.

Introduction:

Raspberry Pi is a small, affordable, credit-card-sized single-board computer (SBC) developed by the Raspberry Pi Foundation in the UK. Unlike Arduino (which is a microcontroller), Raspberry Pi is a fully functional microcomputer that can run a complete operating system — Raspberry Pi OS, based on Debian Linux. It was originally designed to teach computer science in schools, but it has become enormously popular in IoT, AI/ML projects, home automation, media centers, and industrial applications because of its powerful processor and rich connectivity options.

Raspberry Pi Architecture (Pi 4):

- Processor: ARM Cortex-A72 (quad-core 64-bit processor).
- Clock Speed: 1.5 GHz.
- RAM: 1 GB, 2 GB, 4 GB, or 8 GB LPDDR4.
- Storage: MicroSD card (no onboard flash — OS and data stored on microSD).
- Operating System: Raspberry Pi OS (Linux-based, Debian).
- Connectivity: 2× USB 3.0, 2× USB 2.0, HDMI, Ethernet, Wi-Fi 802.11ac, Bluetooth 5.0.
- GPIO: 40 pins — digital I/O, PWM, I2C, SPI, UART.
- Power Supply: 5V via USB-C.

Programming:

Raspberry Pi supports multiple programming languages — Python (most popular for IoT), C/C++, Java, Scratch, and more. Development environments include Thonny (Python), Geany (C/C++), and BlueJ (Java). Being a full Linux computer, Raspberry Pi also supports all standard Linux tools, packages, and command-line operations.

Applications:

- Simple: Media center (Kodi), retro gaming (RetroPie), file server, desktop computer.
- Complex: AI and Machine Learning at the edge, home automation hub, web server, industrial Human-Machine Interface (HMI), drone controller, fog computing node in IoT systems.

Q3. [8 Marks] Draw and explain the Architecture of Arduino.

Introduction:

The Arduino Uno is built around the ATmega328P microcontroller chip. Its architecture is designed for simplicity, reliability, and ease of use in embedded systems and IoT projects. Understanding the architecture helps in designing efficient IoT hardware systems. The Arduino architecture can be explained through its major hardware components and their interconnections.

Core Components of Arduino Architecture:

1. ATmega328P Microcontroller:

This is the brain of the Arduino Uno. It is an 8-bit RISC microcontroller running at 16 MHz. Inside the ATmega328P:

- CPU: 8-bit AVR RISC core. Executes one instruction per clock cycle for most instructions. Has 32 general-purpose 8-bit registers (r0–r31).
- Flash Memory (32 KB): Non-volatile program memory where the Arduino sketch (uploaded code) is stored permanently. 0.5 KB is reserved for the bootloader.
- SRAM (2 KB): Volatile runtime memory used for variables, function calls, and stack during program execution. Data is lost when power is removed.

- EEPROM (1 KB): Non-volatile data memory. Can store data that must survive power loss — like calibration values or settings.
- 10-bit ADC: 6-channel ADC for reading analog sensor voltages (0–5V). Converts to 0–1023 digital values.
- 16-bit Timer/Counters: Used for PWM generation, precise timing, and interrupts.
- USART: For serial communication with computer or other modules.
- SPI and I2C: For communicating with sensors and peripherals.

2. Crystal Oscillator (16 MHz):

Provides the timing signal for the CPU and all peripherals. Every operation — reading a pin, executing an instruction, measuring time — is synchronized to this 16 MHz clock. Higher clock speed = more instructions per second.

3. Power Regulation Circuit:

Arduino can be powered either via USB (5V from computer) or an external power supply (7–12V DC). The onboard voltage regulator steps the external voltage down to the 5V operating voltage required by the ATmega328P. A 3.3V regulator also provides 3.3V for 3.3V sensors.

4. USB-to-Serial Chip (ATmega16U2):

This chip converts USB communication from the computer into UART serial communication that the ATmega328P understands. It serves two purposes: allows the Arduino IDE to upload new programs to the board, and allows the Serial Monitor to display data from Serial.print() statements.

5. Digital I/O Pins (14):

These are the GPIO pins that can be configured as INPUT or OUTPUT. 6 of these (pins 3, 5, 6, 9, 10, 11) support PWM (Pulse Width Modulation) — used for variable brightness LEDs and motor speed control.

6. Analog Input Pins (6 — A0 to A5):

Connected to the ATmega328P's 10-bit ADC. Used for reading analog sensors like LM35, LDR, potentiometer. Returns values 0–1023.

7. ICSP (In-Circuit Serial Programming) Header:

Allows direct programming of the ATmega328P using an external programmer, bypassing the bootloader. Used for advanced low-level programming.

Architecture Diagram Description:

Power Input → Voltage Regulator → 5V Rail. 16 MHz Crystal → ATmega328P CPU. ATmega328P ↔ USB Chip ↔ USB Connector (for programming and serial comm). ATmega328P → Digital Pins (D0–D13). ATmega328P → Analog Pins (A0–A5) → ADC. ATmega328P ↔ I2C/SPI/UART interfaces.

Q4. [4 Marks] **Draw and explain the Architecture of Raspberry Pi.**

Introduction:

Raspberry Pi is a single-board computer (SBC) — all the components of a fully functional computer are mounted on a single circuit board approximately the size of a credit card. Its architecture is significantly more complex than Arduino because it includes all the components needed to run a complete operating system. The Raspberry Pi 4 Model B is the most widely used version in IoT projects.

Key Architectural Components:

1. SoC (System on Chip) — BCM2711:

The Broadcom BCM2711 SoC is the core of Raspberry Pi 4. It contains: ARM Cortex-A72 quad-core 64-bit CPU running at 1.5 GHz, VideoCore VI GPU for graphics and video processing, and memory management and bus controllers. The SoC approach integrates multiple components into one chip, reducing board size and power consumption.

2. RAM:

Separate LPDDR4 RAM chip (1/2/4/8 GB options) soldered adjacent to the SoC. This is the main working memory for the operating system, applications, and data currently in use.

3. MicroSD Card Slot:

Raspberry Pi has no built-in flash storage. The OS (Raspberry Pi OS) and all user data are stored on a MicroSD card. The SD card slot connects directly to the SoC via a high-speed interface.

4. 40-Pin GPIO Header:

A row of 40 pins for interfacing with external hardware. Includes: Digital I/O pins (3.3V logic), PWM pins, I2C buses (SDA, SCL), SPI buses (MOSI, MISO, SCLK, CS), UART (TX, RX), and power pins (3.3V, 5V, GND). Unlike Arduino, Raspberry Pi GPIO operates at 3.3V — connecting 5V sensors directly can damage the Pi.

5. Connectivity Ports:

- 2× USB 3.0 + 2× USB 2.0 ports for peripherals.
- 2× micro-HDMI ports for display output (up to 4K).
- Ethernet RJ45 port for wired network connection.
- Wi-Fi 802.11ac (dual-band) and Bluetooth 5.0 built-in.
- USB-C power input (5V, 3A required for Pi 4).

6. Camera and Display Connectors (CSI/DSI):

CSI (Camera Serial Interface) connector for the Raspberry Pi Camera Module. DSI (Display Serial Interface) connector for the official Raspberry Pi touchscreen display.

Architecture Diagram Description:

BCM2711 SoC (CPU + GPU) ↔ RAM. SoC ↔ MicroSD Slot. SoC ↔ 40-pin GPIO. SoC ↔ USB Controller → USB Ports. SoC ↔ Ethernet Controller → RJ45. SoC ↔ Wi-Fi/BT chip. SoC ↔ HDMI → Display. USB-C → Power Management → 5V Rail.

Q5. [8 Marks] What is Arduino? Explain Programming and Applications in Arduino.

What is Arduino?

Arduino is an open-source hardware and software platform designed to make electronics and programming accessible to everyone — from beginners to professionals. An Arduino board is a physical microcontroller board based on the ATmega328P (for Arduino Uno) that reads inputs from sensors and buttons and turns them into outputs — like activating a motor, turning on an LED, or publishing data to the cloud. The Arduino platform includes both the hardware board and the Arduino Software IDE used for programming.

Arduino was designed with three goals: easy to use (minimal electronics knowledge required), flexible (works with hundreds of sensors and modules), and open-source (design and software are freely available and can be modified). These qualities have made Arduino the most popular prototyping and IoT development platform in the world.

Arduino Programming:

Arduino is programmed using Arduino IDE — a free, cross-platform software that runs on Windows, macOS, and Linux. Programs for Arduino are called 'sketches.' The programming language is based on C/C++ with simplified syntax and built-in libraries.

Structure of an Arduino Program:

setup() Function: This function runs once when the Arduino is powered on or reset. It is used to initialize settings — setting pin modes (INPUT or OUTPUT), starting serial communication, initializing libraries.

loop() Function: This function runs continuously in an infinite loop after setup() completes. It contains the main logic of the program — reading sensors, making decisions, sending data, controlling outputs.

Key Arduino Functions:

- pinMode(pin, mode) — configures a pin as INPUT or OUTPUT.
- digitalWrite(pin, value) — sets a digital output pin to HIGH or LOW.
- digitalRead(pin) — reads the state of a digital input pin (HIGH or LOW).
- analogRead(pin) — reads an analog voltage from A0–A5 (returns 0–1023).
- analogWrite(pin, value) — outputs PWM signal (0–255) on PWM-capable pins.
- delay(ms) — pauses execution for the specified number of milliseconds.

- millis() — returns the number of milliseconds since the Arduino started (used for non-blocking timing).
- Serial.begin(9600) — initializes serial communication at 9600 baud.
- Serial.print() / Serial.println() — sends text to the Serial Monitor.

Sample Code — Temperature Sensor with Alert:

```
void setup() { Serial.begin(9600); pinMode(13, OUTPUT); }
void loop() { int val = analogRead(A0); float temp = (val * 5.0 / 1024) * 100;
if(temp > 40) { digitalWrite(13, HIGH); } else { digitalWrite(13, LOW); }
delay(1000); }
```

Applications of Arduino:

- Simple Projects: Blinking LED, temperature/humidity monitoring, ultrasonic distance measurement, servo motor control.
- IoT Projects: Weather station, smart irrigation system, home automation sensor node, smart dustbin.
- Robotics: Line-following robot, obstacle-avoiding robot, robotic arm.
- Industrial: Conveyor belt control, process monitoring, industrial alarm systems.

Q6. [8 Marks] What is Raspberry Pi? Explain Programming and Applications in Raspberry Pi.

What is Raspberry Pi?

Raspberry Pi is a series of small, affordable single-board computers developed by the Raspberry Pi Foundation in the UK, first released in 2012. It was originally designed to promote computer science education in schools but quickly became one of the most popular computing platforms for IoT, AI/ML, home automation, and hobbyist projects. Raspberry Pi is not a microcontroller like Arduino — it is a complete microcomputer that runs a full Linux-based operating system and can execute complex programs, run web servers, process images, and perform machine learning inference.

The Raspberry Pi Foundation's mission was to create a low-cost, high-capability computer that would inspire a new generation of programmers and engineers. The result was a credit-card-sized board with a powerful ARM processor, ample RAM, rich connectivity (HDMI, USB, Wi-Fi, Bluetooth, GPIO), and support for multiple programming languages — all for a price that makes it accessible to everyone.

Raspberry Pi Programming:

Raspberry Pi runs Raspberry Pi OS (based on Debian Linux) from a MicroSD card. This gives it the full power of a Linux environment including package management, terminal access, and a wide range of software. It supports multiple programming languages and development environments:

- Python (most popular): Thonny IDE is the default Python editor on Raspberry Pi OS. Python's RPi.GPIO library allows easy control of GPIO pins for IoT interfacing.
- C/C++: Geany IDE for C/C++ programming. wiringPi library for GPIO access in C.
- Java: BlueJ IDE for Java programming.
- Scratch: Visual block-based programming for beginners.

Sample Python Code — LED Blink using GPIO:

```
import RPi.GPIO as GPIO; import time; GPIO.setmode(GPIO.BCM); GPIO.setup(18,
GPIO.OUT)
while True: GPIO.output(18, GPIO.HIGH); time.sleep(1); GPIO.output(18, GPIO.LOW);
time.sleep(1)
```

Key Python GPIO Functions:

- GPIO.setmode(GPIO.BCM) — use BCM (Broadcom) GPIO pin numbering.
- GPIO.setup(pin, GPIO.OUT/IN) — configure pin as output or input.
- GPIO.output(pin, GPIO.HIGH/LOW) — set output pin value.
- GPIO.input(pin) — read input pin value.
- GPIO.cleanup() — reset all GPIO pins to safe state when program ends.

Applications of Raspberry Pi:

- IoT Hub: Acts as a central fog computing node in IoT systems — collects data from multiple Arduino sensors, processes it locally, and sends to cloud.
- AI and Machine Learning: Runs TensorFlow Lite for on-device ML inference — facial recognition, object detection, voice recognition.
- Media Center: Runs Kodi or Plex for home media streaming.
- Web Server: Runs Apache or Nginx to host websites.
- Network Pi-hole: Network-wide ad blocker using DNS.
- Robotics: Controls complex multi-sensor robots with computer vision.
- Industrial: Human-Machine Interface (HMI) for factory control systems.
- Education: Teaching Python, Linux, electronics, and IoT in classrooms.

UNIT 7 — IoT Security

Q1. **[4 Marks]** **Explain IoT Security.**

Introduction:

IoT Security refers to the safeguarding of Internet of Things devices, networks, data, and cloud infrastructure from cyberattacks, unauthorized access, data breaches, and other security threats. As IoT devices become more prevalent in critical areas like healthcare, industrial automation, smart cities, and home security, ensuring their security is no longer optional — it is absolutely essential. A compromised IoT device can not only leak sensitive data but can also be used as a gateway to attack larger systems or cause physical harm if it controls critical infrastructure.

Why IoT Security is Challenging:

IoT security is uniquely challenging compared to traditional IT security for several reasons: IoT devices have very limited computational resources (small CPU, little memory), making it difficult to run heavy security software. They are physically deployed in unsupervised environments where they can be physically accessed or tampered with. They often run outdated firmware and have infrequent or no security updates. The sheer scale of IoT (billions of devices) makes centralized security management extremely complex.

Security Objectives in IoT (CIA Triad):

- Confidentiality: Ensuring that sensitive data collected by IoT devices (health data, location, personal information) is only accessible to authorized parties. Achieved through encryption.
- Integrity: Ensuring that IoT data has not been altered during transmission or storage. Achieved through cryptographic hashing.
- Availability: Ensuring that IoT devices and services are accessible when needed. Protecting against denial-of-service attacks.

Levels of IoT Security:

- Device-level Security: Secure boot, hardware encryption, tamper detection, secure firmware updates.
- Network-level Security: Encrypted communication (TLS/DTLS), secure protocols, network segmentation.
- Cloud-level Security: Secure storage, access control, regular security audits, anti-malware.
- Application-level Security: Secure coding practices, user authentication, role-based access control.

Q2. [4 Marks] Explain various security issues and need for IoT Security.

Introduction:

The rapid proliferation of IoT devices has introduced a wide range of security vulnerabilities and threats that did not exist in traditional computing environments. Understanding these security issues and the reasons why IoT security is necessary is the first step toward building secure IoT systems.

Various Security Issues in IoT:

1. Device Security:

- Firmware Vulnerabilities: Many IoT devices ship with outdated or insecure firmware. Attackers can exploit known vulnerabilities in the firmware to gain control of the device. Example: The Mirai botnet attack of 2016 compromised thousands of IoT devices (cameras, routers) by exploiting default passwords and firmware vulnerabilities, using them to launch a massive DDoS attack.
- Physical Tampering: IoT devices are often deployed in public or unattended locations where attackers can physically access and tamper with them to extract data, modify firmware, or use them as attack launching points.

2. Network Security:

- Unsecured Communication: If data is transmitted without encryption, attackers can intercept communications (man-in-the-middle attack) and read or modify sensitive IoT data.
- Weak Authentication: Many IoT devices use simple or default passwords. Attackers can easily gain unauthorized network access.

3. Data Security:

- Data Breaches: Unauthorized access to stored IoT data — health records, location history, personal patterns — can cause serious privacy violations.
- Data Integrity Attacks: Attackers modify sensor data during transmission, causing the IoT system to make wrong decisions (e.g., falsifying temperature readings to disable a cooling system).

4. Cloud Security:

- Insecure APIs: IoT cloud platforms expose APIs for device management. Poorly secured APIs can be exploited to gain unauthorized access.

Need for IoT Security:

- Protecting Sensitive Data: Health data, financial data, personal location data collected by IoT devices must be protected.
- Ensuring Device Functionality: Cyberattacks on IoT devices can disrupt critical services — a cyberattack on medical IoT equipment could harm patients.
- Compliance: Data protection regulations (GDPR in Europe, HIPAA in healthcare) mandate IoT data security.
- User Trust: Users will only adopt IoT technology if they trust that their data and devices are secure.

Q3. [8 Marks] Draw and explain the Architecture of IoT Security.

Introduction:

The IoT Security Architecture is a multi-layer framework that applies security measures at each layer of the IoT system — from the physical device level all the way to the cloud and application level. This layered approach ensures that even if one layer's security is breached, other layers continue to protect the system. No single security measure is sufficient on its own — comprehensive IoT security requires protection at every layer.

IoT Security Architecture — Four Layers:

Layer 1 — Device Layer (Physical Security):

This is the lowest layer, consisting of the actual IoT sensors, actuators, and controllers deployed in the physical environment. Security measures at this layer:

- Secure Boot: The device verifies the integrity of its firmware before booting, ensuring no tampered or malicious firmware is loaded.
- Hardware Encryption: Dedicated hardware security modules (HSM) or ARM TrustZone technology store cryptographic keys securely and perform encryption operations in hardware — making key extraction extremely difficult.
- Tamper Detection: Physical tamper-evident seals and sensors detect if the device has been opened or physically attacked. Some devices automatically wipe sensitive data if tamper is detected.
- Unique Device Identity: Each IoT device has a unique cryptographic identity (certificate or token) embedded during manufacturing.

Layer 2 — Network Layer (Communication Security):

This layer handles the security of data as it travels between IoT devices, gateways, and cloud. Security measures:

- Encryption: All communication is encrypted using TLS (for TCP-based protocols like MQTT) or DTLS (for UDP-based protocols like CoAP). This prevents eavesdropping and man-in-the-middle attacks.
- Mutual Authentication: Both the IoT device and the server authenticate each other using digital certificates before exchanging data. This prevents unauthorized devices from connecting.
- Network Segmentation: IoT devices are isolated in their own network segment (VLAN) — separated from critical business systems so that a compromised IoT device cannot access sensitive corporate data.
- Firewalls and Intrusion Detection Systems (IDS): Monitor network traffic for anomalous behavior that may indicate an attack.

Layer 3 — Cloud Layer (Data Security):

This layer secures IoT data stored and processed in the cloud. Security measures:

- Data Encryption at Rest: IoT data stored in cloud databases is encrypted using AES-256. Even if an attacker gains access to the database, they cannot read the data without the decryption key.
- Access Control: Role-Based Access Control (RBAC) ensures that each user or application can only access the data and functions they are explicitly authorized for.
- Regular Security Audits: Periodic vulnerability assessments and penetration testing of cloud infrastructure.
- Anti-malware and Threat Detection: Cloud security services (AWS GuardDuty, Azure Security Center) monitor for threats in real-time.

Layer 4 — Application Layer (App Security):

This layer secures the applications that users interact with to monitor and control IoT devices. Security measures:

- Secure Authentication: Multi-factor authentication (MFA) for user logins.
- Secure API Design: IoT cloud APIs use OAuth 2.0 and JWT tokens for authorized API access.
- Secure Coding Practices: Applications are developed following secure coding guidelines to prevent SQL injection, XSS, and other vulnerabilities.
- User Authorization: Users can only control devices they are authorized to access.

Security Architecture Diagram Description:

IoT Device (Secure Boot, Hardware Encryption, Tamper Detection) → Network (TLS/DTLS Encryption, Mutual Authentication, Network Segmentation) → Cloud (AES Encryption at Rest, RBAC, Security Audits) → Application (MFA, OAuth, Secure APIs) → Authorized User

Q4. [4 Marks] Explain the requirements of IoT Security.

Introduction:

For an IoT system to be considered secure, it must meet a specific set of security requirements at every layer of its architecture — from the physical device to the cloud application. These requirements define the minimum standards that must be implemented to protect IoT devices, data, and networks from threats.

Key Security Requirements:

1. Authentication:

Every IoT device and user must prove their identity before being allowed to communicate with the system or access data. Strong authentication methods include: device certificates (X.509 certificates embedded during manufacturing), token-based authentication (JWT tokens for API access), and multi-factor authentication (MFA) for human users. Weak authentication (default passwords, no authentication) is one of the leading causes of IoT security breaches.

2. Authorization:

Once authenticated, entities must only be granted access to the resources and functions they specifically need — this is the principle of least privilege. Role-Based Access Control (RBAC) is used to define what each authenticated user or device can do. For example, a temperature sensor should only be able to publish temperature readings — it should not be able to access medical records or control a door lock.

3. Data Encryption:

All sensitive data must be encrypted both in transit and at rest. TLS/DTLS for data in transit, AES-256 for data at rest. Encryption ensures that even if data is intercepted or the storage is breached, the data is unreadable without the correct decryption key.

4. Intrusion Detection:

IDS (Intrusion Detection Systems) must be deployed to continuously monitor IoT device behavior and network traffic for anomalies that may indicate an attack. For example, if an IoT device suddenly starts sending data at 100× its normal rate, an IDS would flag this as suspicious.

5. Secure Firmware Updates (OTA):

IoT devices must support secure Over-The-Air (OTA) firmware updates so that security patches can be applied without physical access. The update mechanism must verify the authenticity and integrity of the firmware before applying it.

6. Physical Security:

Physical measures to prevent unauthorized physical access to IoT devices — tamper-evident casings, physical locks, tamper detection sensors that wipe sensitive data if the device is opened without authorization.

Q5. [8 Marks] Explain the challenges and algorithms of IoT Security.

Introduction:

IoT security faces unique challenges that do not exist in traditional IT security. At the same time, various cryptographic algorithms have been developed or adapted to provide security functions within the constraints of IoT devices. Understanding both the challenges and the solutions (algorithms) is essential for designing secure IoT systems.

Challenges in IoT Security:

1. Resource Constraints:

The most fundamental challenge in IoT security is that most IoT devices have extremely limited computational resources: small CPU (8-bit or 16-bit running at a few MHz), very little RAM (a few KB), limited battery capacity, and small storage. Running traditional security algorithms like RSA-2048 on such devices is impractical — it would take too long and drain the battery. This requires the development of lightweight cryptographic algorithms specifically designed for constrained devices.

2. Scalability:

Managing security for billions of IoT devices is an enormous operational challenge. How do you issue and manage unique security certificates for a billion devices? How do you push firmware security patches to millions of devices efficiently? How do you monitor anomalous behavior across billions of devices? Centralized security management systems can become bottlenecks at this scale.

3. Interoperability:

IoT ecosystems typically consist of devices from many different manufacturers using different communication protocols and security mechanisms. Ensuring consistent security across this diverse landscape is very difficult. A security weakness in one type of device can compromise the entire system.

4. User Awareness:

Many IoT users do not understand security risks. They use default passwords, never update firmware, and connect insecure devices to their home or corporate networks. Human behavior remains one of the biggest security vulnerabilities in IoT.

5. Regulatory Compliance:

Different countries and industries have different regulations for IoT security — GDPR (Europe), HIPAA (US healthcare), NIST IoT security guidelines, etc. Building IoT systems that comply with all applicable regulations across multiple markets is complex and expensive.

6. Physical Environment:

IoT devices deployed outdoors, in industrial environments, or in public spaces are vulnerable to physical attack. Unlike servers in secured data centers, IoT devices often cannot be physically protected.

Security Algorithms for IoT:

1. Symmetric Encryption — AES (Advanced Encryption Standard):

AES is the most widely used encryption algorithm for IoT data protection. It uses the same key for both encryption and decryption (symmetric). AES-128 and AES-256 are common variants. AES is fast and relatively efficient even on constrained hardware — many ARM processors include hardware AES acceleration. Used for: encrypting data stored on IoT devices, encrypting data in transit (as part of TLS/DTLS), and encrypting data at rest in the cloud.

2. Asymmetric Encryption — RSA (Rivest-Shamir-Adleman):

RSA uses a key pair: a public key for encryption and a private key for decryption. It is used for secure key exchange and digital signatures. RSA-2048 provides strong security but is computationally expensive — challenging for very constrained IoT devices. Used for: establishing secure connections (key exchange in TLS handshake), signing firmware updates to verify authenticity.

3. Elliptic Curve Cryptography (ECC):

ECC provides the same security level as RSA but with much smaller key sizes (256-bit ECC ≈ 3072-bit RSA in security strength). This makes ECC significantly more efficient for IoT devices with limited processing power and memory. ECC-based ECDSA (Elliptic Curve Digital Signature Algorithm) is widely used in IoT TLS certificates.

4. Hashing — SHA-256 (Secure Hash Algorithm):

SHA-256 is a one-way cryptographic hash function that produces a fixed 256-bit hash value from any input. It is used for data integrity verification — if even one bit of data changes, the hash value changes completely. Used in IoT for: verifying firmware update integrity (before applying an update, the device checks that its SHA-256 hash matches the expected value), message authentication codes (HMAC-SHA256), and secure password storage.

5. Lightweight Cryptography:

For extremely constrained IoT devices (e.g., simple 8-bit microcontrollers with 8KB RAM), even AES can be too heavy. NIST has standardized lightweight cryptographic algorithms specifically for constrained devices: ASCON (selected as NIST's lightweight cryptography standard in 2023), SIMON and SPECK (designed by NSA for constrained hardware), and PRESENT (ultra-lightweight block cipher). These algorithms provide adequate security with significantly reduced computational and memory requirements.

6. Public Key Infrastructure (PKI):

PKI is the framework for managing digital certificates and public-key encryption in IoT. Each IoT device receives a unique X.509 certificate during manufacturing that cryptographically proves its identity. A Certificate Authority (CA) — either the device manufacturer or a trusted third party — issues and manages these certificates. PKI enables mutual authentication between IoT devices and cloud servers, ensuring that only legitimate devices can connect to the system and only the authorized cloud can receive device data.
